Apply Command to Each Item
in a List of Arguments in “\TeX’s Gullet”*

Uwe Lück†

November 14, 2015

Abstract
This package provides macros for applying a “command” to all items in
a “list of possible macro arguments,” and also for extending and reducing
macros storing such lists. “Brace groups” are single items of such lists, as
opposed to token lists. Iteration is implemented within \TeX’s expansion
processor, so works within \texttt{\write} as with \texttt{blog.sty}. Loop and list macros
in other packages are discussed in the documentation. There is no need
for e-\TeX{} to which some of them refer.

The package is “generic,” i.e., should also work with Plain \TeX or
even other formats, relying on the \texttt{plainpkg} package for some minimal
\LaTeX{}-like behaviour.

\textbf{Related packages:} \texttt{catoptions \texttt{etextools \texttt{etoolbox \texttt{forarray \texttt{forloop \texttt{loops \texttt{multido \texttt{moredfs \texttt{lmake \texttt{texapi \texttt{xfor \texttt{xspace}

\textbf{Keywords:} programming structures; macro programming, loops, list
macros

*This document describes version v0.3 of dowith.sty as of 2012/11/05.
†http://contact-ednotes.sty.de.vu
1 Usage and Features

1.1 Installing and Calling

The file dowith.sty is provided ready, installation only requires putting it somewhere where \TeX{} finds it (which may need updating the filename database).\footnote{http://www.tex.ac.uk/FAQ-inst-wlcf.html}

The packages \texttt{plainpkg}\footnote{http://ctan.org/pkg/plainpkg} and \texttt{stacklet (catcodes)}\footnote{http://ctan.org/pkg/catcodes} must be installed as well.

As to calling (loading): dowith is a "\texttt{plainpkg} package" in the sense of the \texttt{plainpkg} documentation that you may consult for details. So roughly,

- load it by \texttt{\usepackage{dowith}} if you can,
- otherwise by \texttt{\RequirePackage{dowith}} (perhaps from within another "\texttt{plainpkg} package"),
- or by \texttt{\input*dowith.sty}

1.2 What It Does With What Lists

The single commands that the package provides are described in the implementation section below. What follows here is some general background about how the commands work.

The term ‘list’ may refer to various things and need clarification here.

First of all, we are not referring to \LaTeX list environments such as \texttt{enumerate} or \texttt{itemize}; neither to “TODO” lists of what needs to be done soon.

Rather, \texttt{dowith} allows you to abbreviate

\[
\langle \texttt{cmd}\rangle\langle \texttt{arg-1}\rangle\langle \texttt{cmd}\rangle\langle \texttt{arg-2}\rangle\ldots\langle \texttt{cmd}\rangle\langle \texttt{arg-n}\rangle
\]

by

\[
\texttt{DoWith}(\texttt{cmd})\langle \texttt{arg-1}\rangle\langle \texttt{arg-2}\rangle\ldots\langle \texttt{arg-n}\rangle\texttt{\StopDoing}
\]

or by

\[
\texttt{DoWithAllOf}(\texttt{cmd})\{\langle \texttt{arg-1}\rangle\langle \texttt{arg-2}\rangle\ldots\langle \texttt{arg-n}\rangle\}
\]

With small \(n\), one may doubt whether this really is an abbreviation . . . ; anyway,

\[
\langle \texttt{arg-1}\rangle\langle \texttt{arg-2}\rangle\ldots\langle \texttt{arg-n}\rangle
\]

was an attempt to refer to the kind of lists we are dealing with.

\[
\langle \texttt{arg-1}\rangle, \langle \texttt{arg-2}\rangle, \ldots, \langle \texttt{arg-n}\rangle
\]

are the “items” of the list. The question is: what counts as an item?

We might say that \texttt{aa} is a list of two items, \langle \texttt{arg-1}\rangle being \texttt{a} and \langle \texttt{arg-2}\rangle being \texttt{a}, too.

When we do \texttt{three} keystrokes to get \texttt{a_a} instead of \texttt{aa}, we still have \texttt{two} items, \langle \texttt{arg-1}\rangle being \texttt{a} and \langle \texttt{arg-2}\rangle being \texttt{a} too. Strange, isn’t it?

Also, when in \texttt{aa} we replace the first \texttt{a} by a backslash, \texttt{	extbackslash}, we get \texttt{	extbackslash a}, and this is a list of a single item, \langle \texttt{arg-1}\rangle = \texttt{	extbackslash a} . . .

You shouldn’t believe these stories of mine entirely. What I am alluding to is that the “items” \texttt{dowith} is about are determined in terms of \TeX’s tokens, and the relation between the “characters you type” and \TeX’s tokens is not entirely straightforward.

1.3 The Notion of Arglists for \LaTeX Users

Still, it may suffice to clarify what counts as an \langle \texttt{arg-i}\rangle without speaking of tokens explicitly: It is simply what a one-parameter macro (where the parameter is not delimited in terms of \textit{The \TeXbook} pp. 203f.) can take as an argument.

The lists \texttt{dowith} is about then are lists of possible arguments in the previous sense—let me call them “arglists.”\footnote{Not to be confused with German Arglist.} The single items of such lists are those single
possible arguments. They become actual arguments beginning from the leftmost possible one when \texttt{dowith} presents them to that \langle cmd \rangle mentioned earlier—where \langle cmd \rangle should be a one-parameter macro (or some \TeX primitive parsing arguments similarly).

The reader perhaps has an intuitive understanding of what can be an argument of a one-parameter macro. A strict \LaTeX user may think that such an argument \langle arg-i \rangle just has form \{\langle ark-i \rangle\}, i.e., \langle arg-i \rangle = \{\langle ark-i \rangle\} for some \langle ark-i \rangle. Such arguments are also called “brace groups.” (\LaTeX’s optional arguments \{\langle extra \rangle\} do not count as possible arguments here, they are not macro arguments in the sense of \textit{The \TeXbook}.) In this restricted \LaTeX sense, arglists consist of brace groups

\[
\{\langle ark-1 \rangle\} \{\langle ark-2 \rangle\} \ldots \{\langle ark-n \rangle\},
\]

and each single brace group is an item of it.

The \TeX macro writer, by contrast, knows that a macro argument doesn’t need outer braces. In an intuitive sense, a single “command” can be a macro argument, too. “Command” may be understood as “control sequence” (starting with a backslash), but some authors also have considered single characters (character\ tokens?) “commands.” Blank spaces, by contrast, are ignored when a macro looks for its argument.

\subsection{Anatomy of \TeX}

The documentation of v0.22 as of 2012-06-04 said that the package is about “lists in \TeX’s mouth.” However, this was very wrong. I believed it following Alan Jeffrey’s paper “Lists in \TeX’s Mouth”\footnote{Alan Jeffrey: “Lists in \TeX’s Mouth,” TUGboat Vol. 11 (1990), No. 2, pp. 237–245), \url{http://tug.org/TUGboat/tb11-2/tb28jeffrey.pdf}} in whose Section 2 you read:

\TeX’s programming facilities come in two forms—there are \TeX’s macros which are expanded in its mouth, and some additional assignment operations like \texttt{\textbackslash def} which take place in the stomach.

The macros that Jeffrey lists and describes in that article can be obtained as a \CTAN package \texttt{lambda-lists}\footnote{http://ctan.org/pkg/lambda-lists}. If you follow the link given here (in the footnote), you currently (2012-11-03) read about this package:

These list-processing macros avoid the reassignments employed in the macros shown in Appendix D of the \TeXbook: all the manipulations take place in what Knuth is pleased to call “\TeX’s mouth”.

But Knuth doesn’t. On page 267 of \textit{The \TeXbook}, you read:

\textit{Chapter 7 has described the process by which input files are converted to lists of tokens in \TeX’s “mouth,” and Chapter 20 explained how expandable tokens are converted to unexpandable ones in \TeX’s “gullet” by a process similar to regurgitation.}
1 USAGE AND FEATURES

I.e., the “mouth” is \TeX’s “tokenizer,” the inner part of what van Eijkhout calls \TeX’s “input processor” on, e.g., p. 15 of his \TeX by Topic.\footnote{It is available as a CTAN package \texttt{texbytopic} at \url{http://ctan.org/pkg/texbytopic}} The exact rules the tokenizer follows are described on pp. 46f. (Chapter 8!) of The \TeXbook. Macro expansion takes place in \TeX’s “gullet”, which van Eijkhout calls \TeX’s “expansion processor” (p. 16). Abrahams, Hargreaves, and Berry follow Knuth’s terminology on pp. 16 and 46f. of their \TeX for the Impatient.\footnote{It is available as CTAN package \texttt{impatient}, \url{http://ctan.org/pkg/impatient}}

\TeX’s gullet has been called “\TeX’s mouth” also in the documentation of my \texttt{bitelist}\footnote{\url{http://ctan.org/pkg/bitelist}} package and in the documentation of the package \texttt{bibleref-mouth}.

Moreover, I should have clarified that Jeffrey’s paper deals with “lists” in some general, rather abstract sense, different from the kind of lists the present documentation tries to characterize as the objects for \texttt{dowith}.

1.5 \TeX’s Tokens

The \texttt{dowith} package is a tool that affects the order of tokens in \TeX’s gullet.

The “characters you type” enter “\TeX’s mouth” line by line, in a slightly modified appearance. Each line forms a \texttt{string}. \TeX takes initial substrings away from it and turns them into \texttt{tokens} that are appended to the right of \TeX’s \texttt{expansion buffer} (“gullet”).

There are two kinds of tokens here: named tokens and character tokens. “Named” tokens usually are referred to as “control sequence tokens” or just “control sequences”—I really want to avoid those horrible confusions from The \TeXbook. There never are any “parameter tokens” in \TeX’s gullet (perhaps unless one considers a one-step macro expansion a two-or-more-step procedure). The character(s) after the escape character until some delimiting character form a \texttt{string} that is the \texttt{name} of the token that is formed—a named token, as I am saying. Character tokens are formed by removing a character from the beginning of the character buffer and appending it to the token buffer paired with its \texttt{category} code.

For every \texttt{string} of characters, there is exactly one (possible) named token whose name the string is.\footnote{“Possible” refers to the fact that \TeX does not store named tokens anywhere before they appear in its gullet, maybe apart from “primitive” tokens that have a “pre-assigned meaning” when a \TeX run starts.—What is more bad with my claim is that the \TeX program by design cannot extend its memory arbitrarily—even not using the “cloud”—, so it doesn’t support tokens whose name lengths are above a certain limit.} It is so common (starting from The \TeXbook) to denote the token whose name is \texttt{⟨string⟩} by \texttt{\langle⟨string⟩⟩}. For instance, the token whose name is \texttt{input} is denoted by \texttt{\langle\langle input⟩⟩}. On the other hand, on page 7 of The \TeXbook \texttt{\langle\langle input⟩⟩} is a “string of characters.” With this notation, it is already difficult to explain what the \texttt{\texttt{\LaTeX}} command \texttt{\DeclareRobustCommand} does or what the difference between a starred \texttt{\LaTeX} command and a starred \texttt{\LaTeX} environment is.\footnote{A reader knowing \texttt{\LaTeX} only thinks that \texttt{\\equation*} is the result of typing a double backslash and a space and that \texttt{\equation*} is the “command” \texttt{\equation} followed by a \texttt{*}.} The \TeXbook makes it worse by saying on page 39: “A control sequence is considered to be a single object that is no longer composed of a sequence of symbols.” So “it depends” whether \texttt{\langle\langle input⟩⟩} is a string of characters or not—it is \texttt{before} tokenization, but \texttt{no longer} afterwards. So if you have two computers and start a \TeX run on each of them with a little difference in time, there will be a moment where \texttt{\langle\langle input⟩⟩} is a string on the one computer but not on the other? This appears to me like saying “When we apply the square root function to the number 4, the number 4 will no longer be the number 4, it will be the number 2 instead.”

\footnote{It is available as a CTAN package \texttt{texbytopic} at \url{http://ctan.org/pkg/texbytopic}.}
The *\TeXbook* does offer an alternative notation for named tokens: “boxing;” so the token whose name is `input` can be denoted by the rather “graphical” notation `[input]` (used only exceptionally)\footnote{The box notation is introduced on page 38 without explanation, as if it explained something.} I would suggest something like `ntok(input)` for clarity and `?input` for brevity.\footnote{I am suggesting the question mark for named tokens since \TeX “must look up the current definition” of a named token according to *The \TeXbook* p. 39, while the meaning of character tokens rather is “fixed,” at least according to *The \TeXbook* p. 39. However, active-character such as .” are in the same situation as named tokens as to this respect. The dot notation may be fine for them, though.}

Named tokens may get into \TeX’s gullet by “tokenization” as described above, i.e., they are drawn from the character buffer. But they also can appear in \TeX’s gullet “from within,” by the manipulation inside \TeX’s gullet.

More formally, those manipulations are called “expansion,” and \TeX’s gullet can be conceived of as a token buffer that is feeded to the right (or end) by tokenization from the character buffer. Expansion means that certain tokens in the token buffer are substituted by other ones. This way tokens may get into \TeX’s gullet that emerged from tokenization a “long time ago”, maybe in a previous run that created the *\TeX’s variant INITEX*; or tokens may appear by some hardwired expansion function.

However, named tokens may get into \TeX’s gullet also by expansion, never having been drawn by tokenization and not being hardwired. This happens by the `\csname` construct. The input code may contain

```
\csname	upni\endcsname
```

This may be converted into 7 tokens entering \TeX’s gullet, the first one being `ntok(csname)`, the last one `ntok(endcsname)`, and five character tokens in between. Due to some function (which I would denote as `*csname`) originally associated with the token `ntok(csname)`, those seven tokens then are replaced by `ntok(tupni)`, the named token whose name is `tupni`. It is not required that the \TeX program knows about a token `ntok(tupni)`, neither anybody must type `\tupni` in any file.\footnote{These considerations may not be essential here, rather a draft for a paper. Using `dowith`, one better just thinks of the arglist items one actually lists.}

### 1.6 Arglists vs. Lists of Tokens—Example

Let us reconsider the examples from Sections 1.2 and 1.3, and pack them into a single example. If you type a file line

```
\a_{a}^{a}\{a\}
```

(eight keystrokes), it should usually be converted into this seven-item list of tokens:

```latex
\a_{11} \uni{10} \a_{11} \text{ntok(a)} \{_{1} a_{11} \}_{2}
```

— with notation from Section 1.5 and *The \TeXbook*’s notation `(char)`(\cat) for the character token that \TeX’s tokenizer forms from `(char)` in the character buffer when `(char)`’s category code is `(\cat)`.
It turns out that the token list in 2 provides an arglist of four items: the token \(a_{11}\) at the first and third place, the named token \(\text{ntok}(a)\), and the entire token list \(\{a_{11}\}_2\) as a single item—a “brace group.” The space token is ignored.\(^{16}\)

You can try this after \texttt{\renewcommand{\a}{A}}\(^{17}\) with \texttt{dowith}:

\[
\texttt{\DoWith\typein{a\text{\textbackslash a}}\StopDoing}
\]

Then \LaTeX{} shows \(a, a, A\) from \(\a\), and another \(a\) from within the braces—\texttt{\typein} (as any macro with arguments) removes them.

I have avoided saying 2 were an arglist of 4 items. The mathematical basic way of writing lists—understood as finite \textit{sequences}—as “comma-separated lists” within \texttt{brackets} may clarify the difference (that the \texttt{juxtaposition notation} tends to conceal). The \texttt{token} list is

\[
(a_{11}, \texttt{\textbackslash a_{10}}, a_{11}, \texttt{\textbackslash ntok(a)}, \{1, a_{11}\}_2)
\]

while the list of macro arguments is

\[
(a_{11}, a_{11}, \texttt{\textbackslash ntok(a)}, \{1, a_{11}\}_2).
\]

2 or 4 simply is \textit{not} an arglist (since neither \(\{1\} \) nor \(\{2\} \) can be a macro argument), and the arglist 5 “provided” by the list of tokens is \textit{not} a list of \textit{tokens}—its final item is a three-item list of tokens, and a token cannot be a list of two or more tokens itself(?!).

\section{Another Notation and the Example’s Steps}

To write token lists easier and hopefully easier to read, I would suggest writing ‘\langle\texttt{char}\rangle’ for the character token that the tokenizer “usually” forms from character \langle\texttt{char}\rangle, i.e., adding the \texttt{standard category code} as in \textit{The \LaTeX{}book} (page 37). Then 2 would read\(^{18}\)

\[
\texttt{.\text{a\texttt{-u}.a}\text{\textbackslash a\texttt{-e}.a}}
\]

and the corresponding arglist is

\[
(\texttt{.\text{a\texttt{-u}.a}\text{\textbackslash a\texttt{-e}.a}}).
\]

In “retrospect,” the result of tokenizing 2 should be

\[
\texttt{\DoWith\typein{.\text{a\texttt{-u}.a}\text{\textbackslash a\texttt{-e}.a}}\StopDoing}
\]

and the intention is that it works like

\[
\texttt{\typein{.\text{a}\text{\textbackslash a}}?\text{\textbackslash a}\text{\textbackslash a}\text{\textbackslash a}}
\]

(The definition of \texttt{\DoWith} in Section 3.3.1 indeed adds surrounding braces, if missing.) However, \LaTeX{} rather tries to work with as few tokens ahead as possible. When it finds \texttt{\DoWith} and the latter’s meaning is the one intended by \texttt{dowith}, it first looks for nothing more than

\(^{16}\)\textit{The \LaTeX{}book} p. 201: “\LaTeX{} doesn’t use single spaces as undelimited arguments.”

\(^{17}\)Otherwise \(\a\) is a one-parameter macro that breaks \texttt{dowith}’s control.

\(^{18}\)See Section 1.5 for the question mark.
the two arguments required by our definition of \DoWith. A few moments later, the token buffer’s content will just be  

\?\typein{\{a\}}?\expandafter\DoWith?\expandafter?\expandafter\typein?\fi

(10)

Next \?\typein{\{a\}} is expanded according to the code for \typein in \latex.ltx. Some unexpandable tokens will emerge and be moved into the “instruction buffer,” and you should get a screen message with a and a prompt. When you have entered something, the remaining \expandafter \DoWith \expandafter \typein \fi will be removed from the character buffer, and it contains only

?\DoWith?\typein

(11)

Another token is ordered from the tokenizer to provide a second argument for expanding \DoWith. The token .\_/uni2423 comes in, but that doesn’t serve as a macro argument. It is removed, and the next token is .a. The same story as before happens, until the named token ?a is found . . .

1.8 Summary of Possible Arglist Items

For 0 ≤ i ≤ 15, let X_i be the set of character tokens of category code i. X_1 is the set of tokens working like {, and X_2 is the set of tokens working like }.

Let E be the set \{3, 4, 6, 7, 8, 11, 12, 13\}. These numbers are the category codes for math, align, parameter, super, sub, letter, other, active respectively. Let X_E be the set of character tokens of category code in E (so \(X_E = \bigcup_{i \in E} X_i\)).

Let \(\circ\) be the concatenation operation among token lists.

The following kinds of token lists form a single arglist item, i.e., can serve as an argument for an undelimited parameter:

1. a named token, or the single-token list consisting of it, if you prefer that;
2. a character token from X_E or the list consisting of it;
3. a brace group. That is a token list meeting the following conditions: (i) its first token is in X_1, (ii) its last token is in X_2, (iii) it has as many occurrences of tokens from X_1 as from X_2, (iv) if it is split as \(\lambda \circ \rho\), there are not more X_2 occurrences in \(\lambda\) than X_1 occurrences in \(\rho\) (“don’t close before opening”).

The second claim can be checked with

\DoWith\typein#\{"a\}\StopDoing

(12)

as to what works. (The claim is not affected by one or two surprises.) Characters with different category codes either are not converted into a character token or are not accepted as macro arguments. The latter applies to “brace” tokens in X_1, X_2 and to the single space token .10.

As to “brace groups”, the third and fourth condition above are intended to say that what is between the two outer tokens is ⟨balanced text⟩ in the sense of The \TeXbook pp. 275f. and 385; i.e., for two tokens a, b and a token list \(\beta\), \(a \circ \beta \circ b\) is a brace group exactly if a is from X_1, b is from X_2, and \(\beta\) is ⟨balanced text⟩. The conditions are more formal than what I can find in The \TeXbook, but still they don’t give me an idea of all possibilities. This should be improved by the following recursive definition:

\[\text{If you use } \DoWithAllOf\typein(a\_a\_a\_a) \text{ instead, the entire token sequence } 8 \text{ will appear in the token buffer “at once.”}\]

\[\text{TODO: Define for representations by maps, or: “Concatenation is about as basic as natural numbers and is understood in terms of axioms rather than by a definition.”—See notes from 2011 (even with attempts with Category theory) the English Wikipedia for sequences—German article too much restricted to maps.}\]

\[\text{Moreover, } \DoWith\typein\StopDoing \text{ tells something about “parameter tokens.”}\]

\[\text{The } \TeXbook \text{ p. 47.}\]
1 USAGE AND FEATURES

B1. The empty list is balanced text. B2. For any token \( t \) not in \( X_1 \) or \( X_2 \), the single-item token list \((t)\) is balanced text. (Such a token is either a named token or a character token from \( X_E \) or the space token.) B3. If \( \alpha \) and \( \beta \) are balanced texts, then \( \alpha \circ \beta \) is balanced text. B4. If \( \beta \) is balanced text, \( a \) is from \( X_1 \), and \( b \) is from \( X_2 \), then \( (a) \circ \beta \circ (b) \) is balanced text. (This is a brace group, and the only way of getting a brace group.) B5. Nothing else is balanced text.

In other words, a token list is a brace group if and only if it is balanced text and starts with a token from \( X_1 \) and ends with a token from \( X_2 \).

1.9 Summary: “Commands” Usable with dowith

In the implementation section, you learn about \( \texttt{DoWith}(\text{cmd}) \), \( \texttt{DoWithAllOf}(\text{cmd}) \), and \( \texttt{DoWithAllIn}(\text{cmd}) \).

\( \LaTeX \) users may type \( \{\langle \text{cmd} \rangle\} \) instead.) What \( \langle \text{cmd} \rangle \)'s are allowed?

1. All one-parameter macros \( \langle \text{cmd} \rangle \) work this way, unless there are programming mistakes outside dowith (also thinking of arguments that take over control from dowith commands before the argument list is finished).

2. Other one-parameter “commands” \( \langle \text{cmd} \rangle \) such as \( \texttt{\LaTeX} \) primitives may work—you must think of the fact that surrounding braces are added. So the primitives \( \texttt{hbox} \) and \( \texttt{vbox} \) work, for instance. \( \texttt{show} \) is an example that doesn’t work at all, it takes the single starting brace token and then confuses \( \texttt{DoWith} \).

3. Some \( \langle \text{cmd} \rangle \)'s taking no argument may make sense, e.g., for getting

   (a) apples,
   (b) pears,
   (c) peaches

   from

   \begin{enumerate}
   \DoWithAllOf{\item}{\{apples,\}{pears,\}{peaches}\}}
   \end{enumerate}

   Recall that \( \item \) at most takes an optional argument.

4. \( \langle \text{cmd} \rangle \) must not take more than one parameter. A different package will support multi-parameter macros.

23 Again, this may be more of a draft for a paper, or notes for it, than package documentation.

24 TODO: in the future, variants not adding braces could be added.
2 Similar Commands in other Packages

2.1 “Heavy” Packages

The \e\-\TeX\-related packages \texttt{etextools} (Florent Chervet), \texttt{etoolbox} (Philipp Lehman), and \texttt{texapi} (Paul Isambert) seem to include and (very much) extend the functionality of \texttt{dowith}. Also the \texttt{\ForEach}... macros of \texttt{forarray} (Christian Schröppel) seem to extend the present \texttt{\DoWith}... commands. Moreover, Ahmed Musa describes such commands as “Parsing ‘tsv’ lists” in documenting his \texttt{catoptions} package. \texttt{moredefs} (Matt Swift) provides list handling commands like the few that are here.\footnote{arrayjobx provides somewhat “exotic” handling of “lists”.} —In October 2012, Ahmed Musa’s \texttt{loops} appeared on CTAN, offering loops of several “categories” about as those that are listed below, very elaborate.—I do not want to load that much. I need and only need something excessively simple, very few lines of code, as presented in Section 3. The next sections somewhat point out single features of loop constructs that I do not want to have.

2.2 Separators

Regarding \La\TeX\ macros in \texttt{latex.ltx}, the basic macro \texttt{\DoWith} of the present package resembles \texttt{\@tfor} very much, which likewise deals with lists without separators. By contrast, \La\TeX\’s \texttt{\@for} deals with comma-separated lists (such as lists of package options). With comma-separated lists, a “string” of characters counts as an item when it is delimited by commas, or by a comma and the list “border,” or spaces may be used as separators additionally. However, when \La\TeX\ analyzes such lists (in \TeX’s gullet”), it uses representations by \texttt{character tokens} of them.

The more recent \texttt{lmake} (Shengjun Pan) provides a key-value syntax for printing lists of complex mathematical expressions easily (using some assignments) as well as defining commands according to a pattern from a list. Those lists are comma-separated.

2.3 “For” Loops vs. “Foreach” Loops

What about \texttt{forloop} (Nick Setzer), \texttt{multido} (Timothy Van Zandt, Rolf Niepraksh, Herbert Voß), and \texttt{xfor} (Nicola Talbot)? \texttt{xfor} is just a reimplementation of \texttt{\@for}. \texttt{forloop} and \texttt{multido} are more close to “real ‘for’ loops” (cf. Wikipedia). Loops of the latter kind go through a certain set as well, but such sets rather consist of \texttt{numbers} and are exhausted by incrementing (or also decrementing) variables (counters). This is essentially not needed (neither helpful) when a list literally is \texttt{enumerated}—such loops are distinguished as “foreach loops.”

2.4 Iterators

So \texttt{DoWith} and \texttt{@tfor} rather provide “foreach” loops. A major difference between them is that the latter uses a “loop variable” or “iterator” to which the elements of the list are assigned. \texttt{DoWith(cmd)} does not use such a loop variable or such assignments and thus is “expandable” at least when \texttt{(cmd)} (and the elements, depending on \texttt{(cmd)}) are expandable. On the other hand, \texttt{@tfor} applies some procedure to the list elements without needing a name for the procedure (or a macro storing the procedure). I wondered whether behind \LaTeX{}’s \texttt{@tfor} (and \texttt{@for}) there was an “ideological” consideration such as “A loop must have a loop variable!” . . .

Hopefully more clearly on “loop variable” vs. our approach: In order to run \texttt{⟨code-before⟩⟨item⟩⟨code-after⟩} on each \texttt{⟨item⟩} of a \texttt{⟨list⟩}, we here define \texttt{do} as \texttt{#1 → ⟨code-before⟩#1⟨code-after⟩} (13) and then run \texttt{do{⟨item⟩}} for each \texttt{⟨item⟩} in \texttt{⟨list⟩} \footnote{Cf. description of procedure in terms of tokens in Section 1.7.}

always replacing \texttt{do{⟨item⟩}} by \texttt{do{⟨item⟩}do}. (14) \texttt{(do} is only an example command that dowith supports especially.) In \texttt{latex.ltx} instead, we find things like

\texttt{@tfor\@tmp:=⟨list⟩do{⟨code-before⟩\@tmp⟨code-after⟩}} (15)

where \texttt{\@tmp} is a macro that is set to be \texttt{⟨item⟩} at each iteration of the loop, by

\texttt{\def\@tmp{⟨item⟩}} (16)

within \texttt{@tforloop}. After that,

\texttt{⟨code-before⟩\@tmp⟨code-after⟩} (17)

from 15 is run.—17 like 15 is stored in a larger macro. \texttt{do} in 15 does not act as a macro, it just delimits a macro parameter in order give a feeling of some familiar programming structure. This organisation of macros is fine when the loop body code is only used by the containing macro, while the dowith approach to store the “loop body” in an own macro has been useful when the loop body code also is used for different purposes or when it has been introduced before I thought of using it in a loop.

Note that this only was an example. In general, \texttt{⟨item⟩} may appear more than once in the “loop body.”

“Expandability” by avoiding something iterating \texttt{\def\@tmp{⟨item⟩}} and doing iteration in \LaTeX{}’s gullet (\texttt{do} or so must have been defined earlier) is essential especially within \texttt{write}. Assignments do not work there. A major motivation for developing dowith developed with the blog package that \texttt{writes HTML} code. Assignments happen in “\LaTeX{}’s stomach.” That place might be called the “instruction buffer” to which the “expansion processor” moves items from the incoming token buffer that cannot be expanded (any more).
2.5 Separator Macros

Commands like \DoWith also could save tokens thinking of list macros (in \LaTeX/latex.ltx) that use a separator macro which may be used as a command to be applied to the list elements. One example is \dospecials that already is in Plain \TeX and expands to

```
\do\do\do\do\do\do\do\do\do\do\do\do\do\do\do\do\do\do\do\do\do\do\do\do
```

An important application of \dospecials is temporarily switching off the “special” functionality of the “elements” in \dospecials. With \LaTeX, this may happen thus:

```
\let\do\@makeother\dospecials
```

With dowith, you can do the same with a shorter variant \specials of \dospecials, defined by

```
\def\specials{\do\do\do\do\do\do\do}
```

and then

```
\DoWithAllIn\@makeother\specials
```

\latex.ltx uses \@elt instead of \do for its own list macros.

2.6 Ye Olde \loop

There also is [\loop (loop-body)\repeat] in Plain \TeX and a refined version of it in latex.ltx. It is not expandable since it starts with an assignment for \body (Plain \TeX) or \iterate (latex.ltx), and then some assignments are needed to stop the loop, such as incrementing or decrementing a counter. As to the programming structure, it is very simple and general, I think any kind of loop can be implemented by this (apart from nested loops). E.g., I realize that even a “foreach” loop could be implemented by managing a list macro, e.g., using \LaTeX’s internal \@next.

2.7 Without Iterator and Separators

In \LaTeX’s tools bundle, \xspace was developed in the nineties by David Carlisle. It had a rather fixed exception list implemented by a deeply nested conditional. In 2004 Morton Høgholm joined, and now \xspace has a list macro \@xspace@exceptions@tlp without separators. It is handled like here, except that it “breaks” the loop when an item is found that applies. After the “next” token is stored by the usual \futurelet, the exception list is searched without using an iterator. Addition and removal commands are provided as well.

\textsuperscript{27}Using Kabelschacht’s suggestion, cf. Section 4

\textsuperscript{28}2012-05-20
3 IMPLEMENTATION

3 Implementation

3.1 Package File Header (Legalese)

3.2 Proceeding without \LaTeX

v0.3 mainly replaces imitating the german.sty approach to genericity by plainpkg.

\input plainpkg
\ProvidesPackage{\filename}[\filedate space \fileversion space \fileinfo]
\PushCatMakeLetterAt

If \LaTeX is not present . . .

\if\LaTeX \else

. . . an old version of its \in@ is introduced. It is bad as a subword test (false
positive cases, cf. fifinddo documentation), but dowith will check for single tokens
only. If \LaTeX is present, on the other hand, \ifin@ is recognized while skipping
false parts of conditionals, without being matched by some \fi before the next
\else, so I hide it by \csname:

\def\in@\#1\#2{%
  \def\in@##1##2##3\in@{%
    \if\in@##2\in@false else\in@true\fi%}
  \in@##2##1\in@\in@}
\fi
3 IMPLEMENTATION

3.3 Applying a Command

3.3.1 Core

\DoWith\{cmd\}\{list\}\StopDoing applies \texttt{cmd} to all elements of \texttt{list}. An element of \texttt{list} (after tokenizing) may be either a single token or a group \texttt{\{\}}.

\begin{verbatim}
\def\DoWith#1#2{\%\n  \ifx\StopDoing#2\empty
  \else#1{#2}\expandafter\DoWith\expandafter#1\fi}
\end{verbatim}

The previous \texttt{\empty} (replacing \%) is a bug fix as of v0.22 (June 2012), while in my extension draft I already had it in January 2012. It allows “empty” arglist items \texttt{\{\}}. Before v0.22, such an empty brace group would have resulted in comparing \StopDoing with \texttt{\else}, so \texttt{\{\}} would have had the same effect as \StopDoing, the token text after \texttt{\else} until \texttt{\fi} would have been skipped. Instead, the user may have a reason to allow empty arguments/brace groups.

\begin{verbatim}
\else#1#2\empty\StopDoing\expandafter\DoWith\expandafter#1#2\fi}
\end{verbatim}

\StopDoing delimits the list:

\begin{verbatim}
\let\StopDoing\DoWith
\let\StopDoing*\DoWithAllOf
\end{verbatim}

\DoWith\{\do\}\{list\}\StopDoing:

\begin{verbatim}
\def\DoWithAllOf#1#2{\DoWith#1{#2}\StopDoing}
\end{verbatim}

3.3.2 \texttt{\do} being the Command

When the \texttt{\{list\}} is worked at a single time in the \TeX run where assignments are possible, instead of introducing a new macro name for \texttt{cmd} you can use \texttt{\do} for \texttt{cmd} as a “temporary” macro and define it right before

\begin{verbatim}
\DoWith\{\do\}\{list\}\StopDoing
\end{verbatim}

However, we provide

\begin{verbatim}
\DoDoWith\{cmd\}\{list\}\StopDoing
\end{verbatim}

as a substitute for the former line that at least saves one token. For the definition of \texttt{\do}, we provide \begin{verbatim} \setdo\{def-text\}\end{verbatim}. It works similarly to

\begin{verbatim}
\renewcommand\{do\}[1]{\langle def-text\rangle},
\end{verbatim}

so \texttt{\langle def-text\rangle} should contain a \#1:
With \letdo{cmd} that is provided next where \textit{cmd} is defined elsewhere, you could type

\letdo{cmd}\DoWith\StopDoing

It seems to me, however, that you better type

\dowith{cmd}{list}\StopDoing

instead. So I provide \letdo although I consider it useless here. It is provided somewhat for the sake of “completeness,” thinking that it might be useful at other occasions such as preceding \dospecials.

\DoDoWith has been described above:

\DoDoWith\DoWith\StopDoing

By analogy to \DoWithAllOf, we provide \DoDoWithAllOf{list}:

\DoDoWithAllOf\DoWithAllOf\StopDoing

3.3.3 Expand List Macro

The former facilities may be quite useless as such a \textit{list} will not be typed at a single place in the source code, rather the items to run \textit{cmd} on may be collected occasionally when some routines run. The elements may be collected in a macro \textit{list-macro} expanding to \textit{list}. So we provide

\DoWithAllIn\DoWithAll\StopDoing

(or \DoWithAllIn\DoWithAll\StopDoing). There is no need to type \StopDoing here:

\DoWithAllIn\DoWithAll\StopDoing

3.4 Handling List Macros

3.4.1 Initializing

Here is some advanced \let{cmd}\empty, perhaps a little irrelevant for practical purposes. Both

\InitializeListMacro{list-macro}
and

\ReInitializeListMacro{⟨list-macro⟩}

attempt to “empty” ⟨list-macro⟩, and when we don’t believe that \TeX{} has been loaded, both do the same indeed. Otherwise the first one complains when ⟨list-macro⟩ seems to have been used earlier while the second complains when ⟨list-macro⟩ seems not to have been used before:

\ifltx
  \def\InitializeListMacro#1{%\@ifdefinable#1{%\let#1\empty}}
  \def\ReInitializeListMacro#1{%\edef\@tempa{\expandafter\@gobble\string#1}%\expandafter\@ifundefined\expandafter{\@tempa}{\@latex@error{\noexpand#1\@empty\@ehc}}{\let#1\empty}}
\else
  \def\InitializeListMacro#1{\let#1\empty} %% not \@empty 2011/11/07
  \let\ReInitializeListMacro\InitializeListMacro
\fi

\ToListMacroAdd{⟨list-macro⟩}{⟨cmd-or⟩} appends ⟨cmd-or⟩ to the replacement token list of ⟨list-macro⟩. ⟨cmd-or⟩ may either be tokenized into a single token, or it is some {⟨balanced⟩}.

\def\ToListMacroAdd#1#2{\DefExpandStart#1{#1#2}}
\def\DefExpandStart#1{\expandafter\def\expandafter#1\expandafter}  

3.4.2 Testing for Occurrence of a Token

\TestListMacroForToken{⟨list-macro⟩}{⟨cmd⟩} sets \in@true when ⟨cmd⟩ occurs in ⟨list-macro⟩ and sets \in@false otherwise:

\def\TestListMacroForToken#1#2{%\expandafter\in@ \expandafter#2\expandafter#1}\expandafter\expandafter#1#2\expandafter#2\expandafter#1\expandafter

Indeed I removed an earlier \IfTokenInListMacro, now it’s a kind of compromise between having a shorthand macro below and a generalization for users of the package.

3.4.3 Adding and Removing

\FromTokenListMacroRemove{⟨list-macro⟩}{⟨cmd⟩} removes the token corresponding to ⟨cmd⟩ from the list stored in ⟨list-macro⟩ (our parsing method does not work with braces):

\def\FromTokenListMacroRemove#1#2{%  
I am not happy about defining two parser macros, but for now ...
3 IMPLEMENTATION

\TestListMacroForToken#1#2%
\ifin@
\def\RemoveThisToken##1#2{##1}%
\expandafter \DefExpandStart
\expandafter #1\expandafter {%
\expandafter\RemoveThisToken #1}%
\fi}

\TODO warning otherwise?
\}

... but this only removes a single occurrence ...

\InTokenListMacroProvide{(\texttt{list-macro})}{(\texttt{cmd})}

avoids multiple entries of a token by not adding anything when \texttt{(cmd)} already occurs in \texttt{(list-macro)} (again, this does not work with braces, try \texttt{\in@\{}\{\}\{}).

\def\InTokenListMacroProvide#1#2{%
\TestListMacroForToken#1#2%
\ifin@ \else \% TODO warning?
\ToListMacroAdd#1#2%
\fi}

3.5 Leaving and History

\PopLetterCatAt \% v0.3
\endinput

VERSION HISTORY

v0.1 2011/06/23/28 stored separately
v0.2 2011/11/02 simpler, documented
v0.2 2011/11/03 corrected \texttt{\if/\else for init}
v0.2 2011/11/07 \TestListMacroForToken, \InListMacroProvide;
doc.: \texttt{\pagebreak, structure}
v0.21 2012/05/14 fix for "generic" and 'typeoutfileinfo':
\% before ...
\v0.21a 2012/05/19 \texttt{\labels sec:apply, sec:core; \pagebreak?}
v0.22 2012/06/04 allow {} items
v0.3 2012/11/05 updating copyright, using ‘plainpkg’,
rewording documentation there
4 Ack.: 25 Years of Kabelschacht’s \expandafter

The essential idea of dowith and DoWith is

\if(code)\expandafter\one-token\fi

It was described by Alois Kabelschacht as "\expandafter vs. \let and \def in Conditionals and a Generalization of PLAIN’s \loop" in TUGboat Vol. 8 (1987), No. 2, pp. 184f. (a little more than one column). See some German biographical notes on Kabelschacht in the German Wikipedia. It seems to me that Knuth didn’t note this application of \expandafter in The \TeX book. It was then applied in many macros of latex.ltx, cf. source2e.pdf.
