The \texttt{tabularx} package∗

David Carlisle

2020/01/15

Abstract

A new environment, \texttt{tabularx}, is defined, which takes the same arguments as \texttt{tabular*}, but modifies the widths of certain columns, rather than the inter column space, to set a table with the requested total width. The columns that may stretch are marked with the new token \texttt{X} in the preamble argument.

This package requires the \texttt{array} package.

1 Introduction

This package implements a version of the \texttt{tabular} environment in which the widths of certain columns are calculated so that the table is a specified width. Requests for such an environment seem to occur quite regularly in \texttt{comp.text.tex}.

\begin{tabularx}{⟨width⟩}{⟨pos⟩}{⟨preamble⟩}
\end{tabularx}

The arguments of \texttt{tabularx} are essentially the same as those of the standard \texttt{tabular*} environment. However rather than adding space between the columns to achieve the desired width, it adjusts the widths of some of the columns. The columns which are affected by the \texttt{tabularx} environment should be denoted with the letter \texttt{X} in the preamble argument. The \texttt{X} column specification will be converted to \texttt{p⟨some value⟩} once the correct column width has been calculated.

2 Examples

The following table is set with \texttt{\begin{tabularx}{250pt}{|c|X|c|X|} ...}

<table>
<thead>
<tr>
<th>Multicolumn entry!</th>
<th>THREE</th>
<th>FOUR</th>
</tr>
</thead>
<tbody>
<tr>
<td>one</td>
<td>The width of this column depends on the width of the table.\textsuperscript{1}</td>
<td>three</td>
</tr>
</tbody>
</table>

\textsuperscript{1}You can now use \texttt{\footnote} inside \texttt{tabularx}.

∗This file has version number v2.11c, last revised 2020/01/15.
If we change the first line to `\begin{tabularx}{300pt}{|c|X|c|X|}` we get:

<table>
<thead>
<tr>
<th>Multicolumn entry!</th>
<th>THREE</th>
<th>FOUR</th>
</tr>
</thead>
<tbody>
<tr>
<td>one</td>
<td>The width of this column depends on the width of the table.</td>
<td>three</td>
</tr>
</tbody>
</table>

3 Differences between `tabularx` and `tabular*`

These two environments take the same arguments, to produce a table of a specified width. The main differences between them are:

- `tabularx` modifies the widths of the columns, whereas `tabular*` modifies the widths of the inter-column spaces.

- `tabular` and `tabular*` environments may be nested with no restriction, however if one `tabularx` environment occurs inside another, then the inner one must be enclosed by `{ }`.

- The body of the `tabularx` environment is in fact the argument to a command, and so certain constructions which are not allowed in command arguments (like `\verb`) may not be used.

- `tabular*` uses a primitive capability of \TeX to modify the inter-column space of an alignment. `tabularx` has to set the table several times as it searches for the best column widths, and is therefore much slower. Also the fact that the body is expanded several times may break certain \TeX constructs.

4 Customising the behaviour of `tabularx`

4.1 Terminal output

`\tracingtabularx` If this declaration is made, say in the document preamble, then all following `tabularx` environments will print information about column widths as they repeatedly re-set the tables to find the correct widths.

As an alternative to using the `\tracingtabularx` declaration, either of the options `infoshow` or `debugshow` may be given, either in the `\usepackage` command that loads `tabularx`, or as a global option in the `\documentclass` command.

4.2 The environment used to typeset the `X` columns

By default the `X` specification is turned into `p{(some value)}`. Such narrow columns often require a special format, this may be achieved using the `>` syntax of `array.sty`. So for example you may give a specification of `>{(small)}X`. Another format which is useful in narrow columns is ragged right, however \TeX’s `\raggedright` macro redefines `\` in a way which conflicts with its use in a `tabular` or `array` environments. For this reason this package introduces the command `\arraybackslash`, this may be used after a `\raggedright`, `\raggedleft`.

\footnote{Since Version 1.02, `\verb` and `\verb*` may be used, but they may treat spaces incorrectly, and the argument can not contain an unmatched `{` or `}`, or a `%` character.}

2
or `\centering` declaration. Thus a `tabularx` preamble may specify
>`\{\raggedright\arraybackslash\}X`.

\newcolumntype{X}

These preamble specifications may of course be saved using the command,
\newcolumntype{Y}{>`\\small\raggedright\arraybackslash\}X}
and then use Y in the `tabularx` preamble argument.

\tabularxcolumn{X}

The X columns are set using the p column which corresponds to `\parbox[t]`. You may want them set using, say, the m column, which corresponds to `\parbox[c]`. It is not possible to change the column type using the > syntax, so another system is provided. `\tabularxcolumn{X}` should be defined to be a macro with one argument, which expands to the `tabular` preamble specification that you want to correspond to X. The argument will be replaced by the calculated width of a column.

The default is `\newcommand{\tabularxcolumn}[1]{p{#1}}`. So we may change this with a command such as:
`\renewcommand{\tabularxcolumn}[1]{>`\small\m{#1}}`

### 4.3 Column widths

Normally all X columns in a single table are set to the same width, however it is possible to make `tabularx` set them to different widths. A preamble argument of
>`\{hsize=.5\hsize\linewidth=\hsize\}X`
>`\{hsize=1.5\hsize\linewidth=\hsize\}X`

specifies two columns, the second will be three times as wide as the first. However if you want to play games like this you should follow the following two rules.

- Make sure that the sum of the widths of all the X columns is unchanged. (In the above example, the new widths still add up to twice the default width, the same as two standard X columns.)

- Do not use `\multicolumn` entries which cross any X column.

As with most rules, these may be broken if you know what you are doing.

### 4.4 If the algorithm fails...

It may be that the widths of the ‘normal’ columns of the table already total more than the requested total width. `tabularx` refuses to set the X columns to a negative width, so in this case you get a warning “X Columns too narrow (table too wide)”.

The X columns will in this case be set to a width of 1em and so the table itself will be wider than the requested total width given in the argument to the environment. This behaviour of the package can be customised slightly as noted in the documentation of the code section.

### 5 The Macros

1 `(*package)`
2 `\DeclareOption{infoshow}{\AtEndOfPackage\tracingtabularx}`
3 `\DeclareOption{debugshow}{\AtEndOfPackage\tracingtabularx}`
4 `\ProcessOptions`
This requires \texttt{array.sty}. \texttt{\RequirePackage[array]{1994/02/03}}

First some registers etc. that we need. \newdimen\TX@col@width \newdimen\TX@old@table \newdimen\TX@old@col \newdimen\TX@target \newdimen\TX@delta \newcount\TX@cols

Now a trick to get the body of an environment into a token register, without doing any expansion. This does not do any real checking of nested environments, so if you should need to nest one \texttt{tabularx} inside another, the inner one must be surrounded by \{ \}

\texttt{tabularx} Prior to v1.06, this macro took two arguments, which were saved in separate registers before the table body was saved by \texttt{\TX@get@body}. Unfortunately this disables the [t] optional argument. Now just save the width specification separately, then clear the token register \texttt{\toks@}. Finally call \texttt{\TX@get@body} to begin saving the body of the table. The \texttt{\iftnum0=\fi} was added at v1.03, to allow \texttt{tabularx} to appear inside a \texttt{\halign}.

This mechanism of grabbing an environment body does have the disadvantage (shared with the AMS alignment environments) that you can not make extension environments by code such as

\texttt{\newenvironment{foo}{\begin{tabularx}{XX}}{\end{tabularx}}}

as the code is looking for a literal string \texttt{\end{tabularx}} to stop scanning. Since version 2.02, one may avoid this problem by using \texttt{\tabularx} and \texttt{\endtabularx} directly in the definition:

\texttt{\newenvironment{foo}{\tabularx{XX}}{\endtabularx}}

The scanner now looks for the end of the current environment (\texttt{foo} in this example.) There are some restrictions on this usage, the principal one being that \texttt{\endtabularx} must not be inside any \{ \} pairs so that the code before \texttt{\endtabularx} may be extracted and added to the table body (prior to version 2.09 \texttt{\endtabularx} had to be the \textit{first} token of the ‘end code’ of the environment).

\texttt{\edef\tabularx[#1]{}%}

Allow \texttt{\tabularx} \texttt{\endtabularx} (but not \texttt{\begin{tabularx} \end{tabularx}}) to be used in \texttt{\newenvironment} definitions.

\texttt{\edef\TX@{\%currentenv}}\% \texttt{\iftnum0=\fi}

\texttt{\relax} added at v1.05 so that non-expandable length tokens, like \texttt{\textwidth} do not generate an extra space, and an overfull box. \texttt{\relax} removed again at v2.09 in favour of \texttt{\setlength} so if you use the calc package you can use a width of \texttt{(\textwidth-12pt)/2}.

\texttt{\setlength\TX@target[#1]{}%}

\texttt{3}This adds an extra level of grouping, which is not really needed. Instead, I could use \texttt{here}, and \texttt{\iftnum0=\fi} below, however the code here would then have to be moved after the first line, because of the footnote to page 386 of the \LaTeX{}Book, and I do not think I should be writing code that is so obscure as to be documented in a footnote in an appendix called “Dirty Tricks”!
\end{tabularx} This does not do very much...
\let\end{tabularx}\relax
\TX@get@body Place all tokens as far as the first \end into a token register. Then call \TX@find@end to see if we are at \end{tabularx}.
\long\def\TX@get@body#1\end
{\toks@\expandafter{\the\toks@#1}\TX@find@end}
\TX@find@end If we are at \end{tabularx}, call \TX@end{tabularx}, otherwise add \end{...} to the register, and call \TX@get@body again.
\long\def\TX@find@end#1{\def\@tempa{#1}\ifx\@tempa\TX@\expandafter\TX@endtabularx\else\toks@\expandafter{\the\toks@#1}\expandafter\TX@get@body\fi}
\TX@find@endtabularxa split up the end code, and extract the part that lives in the table body.
\long\def\TX@find@endtabularxa
{#1\endtabularx#2\endtabularx#3\TX@find@endtabularxa{\ifx\TX@#2%\expandafter\@firstoftwo\else\expandafter\@secondoftwo\fi}{#1}{#2}}
\TX@find@endtabularxb split up the end code, and extract the part that lives outside the table body.
\long\def\TX@find@endtabularxb
{#1\endtabularx#2\endtabularx#3\TX@find@endtabularxb{\ifx\TX@#2%\expandafter@firstoftwo\else\expandafter@secondoftwo\fi}\fi\{#1}{#2}}
\TX@find@endtabularxbb Helper to avoid needing 15 consecutive expandafter
\def\TX@find@endtabularxbb{% \expandafter@expandafter\expandafter@expandafter\expandafter@expandafter\expandafter@expandafter@expandafter\TX@find@endtabularxb}
\TX@ The string \texttt{tabularx} as a macro for testing with \texttt{latex}.
\def\TX@{tabularx}

Now that all the parts of the table specification are stored in registers, we can begin the work of setting the table.

The algorithm for finding the correct column widths is as follows. Firstly set the table with each \texttt{X} column the width of the final table. Assuming that there is at least one \texttt{X} column, this will produce a table that is too wide. Divide the excess width by the number of \texttt{X} columns, and reduce the column width by this amount. Reset the table. If the table is not now the correct width, a \texttt{\multicolumn} entry
must be ‘hiding’ one of the \(X\) columns, and so there is one less \(X\) column affecting
the width of the table. So we reduce by 1 the number of \(X\) columns and repeat
the process.

\begin{verbatim}
\end{verbatim}

Although I have tried to make \texttt{tabularx} look like an environment, it is in fact a
command, all the work is done by this macro.

\begin{verbatim}
\def\end{tabularx}{% \expandafter\expandafter\expandafter
\end\begin{tabularx}\end{tabularx}\end{tabularx}
\end{verbatim}

Define the \(X\) column, with an internal version of the \texttt{\newcolumntype} command.
The \texttt{\expandafter} commands enable \texttt{\NC@newcol} to get the \texttt{expansion}
of \texttt{\tabularxcolumn{\TX@col@width}} as its argument. This will be the definition
of an \(X\) column, as discussed in section 4.

\begin{verbatim}
\expandafter\NC@newcol\expandafter{\tabularxcolumn{\TX@col@width}}%
\end{verbatim}

Initialise the column width, and the number of \(X\) columns. The number of \(X\)
columns is set to one, which means that the initial count will be one too high, but
this value is decremented before it is used in the main loop.

Since v1.02, switch the definition of \texttt{\verb}.

\begin{verbatim}
\let\verb\NC@verb
\end{verbatim}

Since v1.05, save the values of all \texttt{\LaTeX} counters, the list \texttt{\cl@@ckpt}
contains
the names of all the \texttt{\LaTeX} counters that have been defined so far. We expand
\texttt{\setcounter} at this point, as it results in fewer tokens being stored in \texttt{\TX@ckpt},
but the actual resetting of the counters occurs when \texttt{\TX@ckpt} is expanded after
each trial run. Actually since v1.07, use something equivalent to the expansion
of the original definition of \texttt{\setcounter}, so that \texttt{tabularx} works in conjunction
with \texttt{calc.sty}.

\begin{verbatim}
\def\@elt##1{\global\value{##1}\the\value{##1}\relax}%
\edef\TX@ckpt{\cl@@ckpt}%
\let\@elt\relax
\TX@old@table\maxdimen
\TX@col@width\TX@target
\global\TX@cols\one
\end{verbatim}

Typeout some headings (unless this is disabled).

\begin{verbatim}
\TX@typeout@% \@spaces Table Width\@spaces Column Width\@spaces X Columns}%
\end{verbatim}

First attempt. Modify the \(X\) definition to count \(X\) columns.

\begin{verbatim}
\TX@trial{\def\NC@rewriteX{% \global\advance\TX@cols\one\NC@find p{\TX@col@width}}}%
\end{verbatim}

Repeatedly decrease column width until table is the correct width, or stops shrinking,
or the columns become two narrow. If there are no multicolumn entries, this
will only take one attempt.

\begin{verbatim}
\loop
\TX@arith
\ifTX@%
\TX@trial{}%
\repeat
\end{verbatim}
One last time, with warnings back on (see appendix D) use tabular* to put it in a box of the right size, in case the algorithm failed to find the correct size.

Since v1.04, locally make \footnotetext save its argument in a token register. Since v1.06, \toks@ contains the preamble specification, and possible optional argument, as well as the table body.

\{\let\@footnotetext\TX@ftntext\let\@xfootnotenext\TX@xftntext
 \csname tabular*\expandafter\endcsname\expandafter\TX@target
 \the\toks@
 \csname endtabular*\endcsname\%
\}

Now the alignment is finished, and the } has restored the original meaning of \@footnotetext expand the register \TX@ftn which will execute a series of \footnotetext\{⟨num⟩\}{⟨note⟩}\ commands. We need to be careful about clearing the register as we may be inside a nested tabularx.

\global\TX@ftn\expandafter{\expandafter}\the\TX@ftn

Now finish off the tabularx environment. Note that we need \end{tabularx} here as the \end{tabularx} in the user’s file is never expanded. Now use \TX@ rather than tabularx.

We also need to finish off the group started by \{\ifnum0=‘\}\fi in the macro \tabularx.

\iftX@=‘\fim
 \expandafter\expandafter\expandafter
 \TX@find@endtabularxbb
 \expandafter\end\expandafter{\TX@}
 \endtabularx\TX@find@endtabularxb
 \}

\TX@arith Calculate the column width for the next try, setting the flag \ifTX@false to false if the loop should be aborted.

\\def\TX@arith{%
 \TX@false
 \@tempdimb\maxdimen
 \divide\@tempdimb\TX@cols
 \ifdim\TX@col@width>\@tempdimb

\global\TX@ftn\expandafter{\the\TX@ftn\footnotetext[#1]{#2}}%
\TX@trial@ftn On trial runs, gobble footnote texts.
\long\def\TX@trial@ftn#1{}

This last section was added at Version 1.02. Previous versions documented the fact that \verb did not work inside tabularx, but that did not stop people using it! This usually put \TeX into an irrecoverable error position, with error messages that did not mention the cause of the error. The ‘poor man’s \verb’ (and \verb*) defined here is based on page 382 of the \TeXBook. As explained there, doing verbatim this way means that spaces are not treated correctly, and so \verb* may well be useless, however I consider this section of code to be error-recovery, rather than a real implementation of verbatim.

The mechanism is quite general, and any macro which wants to allow a form of \verb to be used within its argument may \let\verb=\TX@verb. (Making sure to restore the real definition later!)
\verb and \verb* are subject to the following restrictions:

1. Spaces in the argument are not read verbatim, but may be skipped according to \TeX’s usual rules.
2. Spaces will be added to the output after control words, even if they were not present in the input.
3. Unless the argument is a single space, any trailing space, whether in the original argument, or added as in (2), will be omitted.

4. The argument must not end with \, so \verb|\| is not allowed, however, because of (3), \verb|\ | produces \.

5. The argument must be balanced with respect to \{ and \}. So \verb|\{ is not allowed.

6. A comment character like % will not appear verbatim. It will act as usual, commenting out the rest of the input line!

7. The combinations '? and '!' will appear as ¿ and ¡ if the cmnt font is being used.

\TX@verb The internal definition of \verb. Spaces will be replaced by ~, so for the starform, \let ~ be \, which we obtain as \uppercase{\{}. Use \{\ifnum0='\}\fi rather than \bgroup to allow & to appear in the argument.

\TX@vb Get the ‘almost verbatim’ text using \meaning. The ‘!’ is added to the front of the user supplied text, to ensure that the whole argument does not consist of a single \{ \} group. \TeX would strip the outer braces from such a group. The ‘!’ will be removed later.

Originally I followed Knuth, and had \def\@tempa{##1}, however this did not allow # to appear in the argument. So in v1.04, I changed this to use a token register, and \edef. This allows # appear, but makes each one appear twice!, so later we loop through, replacing ## by #.

\TX@v Strip the initial segment of the \meaning, including the ‘!’ added earlier.

As explained above we are going to replace ## pairs by #. To do this we need non-special # tokens. Make * into a parameter token so that we can define macros with arguments. The normal meanings will be restored by the \endgroup later.

\TX@vfirst As a special case, prevent the first character from being dropped. This makes \verb!* | produce \|. Then call \TX@v. This is slightly tricky since v1.04, as I have to ensure that an actual # rather than a command \let to # is passed on if the first character is #.
\verb*|\LaTeX| produces \LaTeX{} not \LaTeX\,\!~. The rewritten tokens are then further processed to replace \## pairs.

\gdef\TX@v@*1 \*2{\TX@v@hash*1##\relax\if*2\\\else~\expandafter\TX@v@fi*2}

\TX@v@hash The inner loop, replacing \## by \#.

\gdef\TX@v@hash*1\*2{\*1\ifx*2\relax\else\#\expandafter\TX@v@hash\fi*2}

As promised, we now restore the normal meanings of \# and \*.

\TX@v@warn Warn the user the first time this \verb is used.

\def\TX@v@warn{%
\@warning{\noexpand\verb may be unreliable inside tabularx}%
\global\let\TX@v@warn\@empty
}

⟨/package⟩
