This is a list of all corrections made to Computers & Typesetting, Volumes A–E, between 16 June 1987 and 20 February 1989. Corrections made to the softcover version of The TEXbook are the same as corrections to Volume A. Corrections to the softcover version of The METAFONTbook are the same as corrections to Volume C. Some of these corrections have already been made in reprints of the books. Some of these corrections affect the indexes and mini-indexes of Volumes B and D in ways not shown here. Corrections made up to 15 June 1987 appear in other files.

Consequently there was plenty of room for more macros: 52821 – 27618 = 25203 unused cells of main memory, 2500 – 1172 = 1328 of name memory, 1685 – 209 = 1476 of string memory, and 17636 – 1659 = 15977 of character memory. But a fairly large \TeX was being used, and only the macros of Appendices B and E were loaded; in other circumstances it might have been necessary to conserve space.

Page A454, lines 23–29 (8/13/87)

If a suitable starting letter is found, let it be in font $f$. Hyphenation is abandoned unless the `\hyphenchar` of $f$ is between 0 and 255, and unless a character of that number exists in the font. If this test is passed, \TeX continues to scan forward until coming to something that’s not one of the following three “admissible items”: (1) a character in font $f$ whose `\lccode` is nonzero; (2) a ligature formed entirely from characters of type (1); (3) an implicit kern. The first inadmissible item terminates this part of the process; the trial word consists of all the letters found in admissible items. Notice that all of these letters are in font $f$.
