The MFT processor

(Version 2.1, January 2021)
1* Introduction. This program converts a METAFONT or METAPOST source file to a \TeX file. It was written by D. E. Knuth in June, 1985; a somewhat similar SAIL program had been developed in January, 1980. Changes for METAPOST by W. Bzyl in July, 2001.

The general idea is to input a file called, say, foo.mf and to produce an output file called, say, foo.tex. The latter file, when processed by \TeX, will yield a “prettyprinted” representation of the input file.

Line breaks in the input are carried over into the output; moreover, blank spaces at the beginning of a line are converted to quads of indentation in the output. Thus, the user has full control over the indentation and line breaks. Each line of input is translated independently of the others.

A slight change to METAFONT’s comment convention allows further control. Namely, ‘%%’ indicates that the remainder of an input line should be copied verbatim to the output; this interrupts the translation and forces \TeX to produce a certain result.

Furthermore, ‘%%% ⟨token1⟩ . . . ⟨token_n⟩’ introduces a change in \TeX’s formatting rules; all tokens after the first will henceforth be translated according to the current conventions for ⟨token1⟩. The tokens must be symbolic (i.e., not numeric or string tokens). For example, the input line

```
%%% addto fill draw filldraw
```

says that the ‘fill’, ‘draw’, and ‘filldraw’ operations of plain METAFONT should be formatted as the primitive token ‘addto’, i.e., in boldface type. (Without such reformatting commands, MFT would treat ‘fill’ like an ordinary tag or variable name. In fact, you need a reformatting command even to get parentheses to act like delimiters!)

METAFONT comments, which follow a single % sign, should be valid \TeX input. But METAFONT material can be included in | . . . | within a comment; this will be translated by \TeX as if it were not in a comment. For example, a phrase like ‘make |x_{2r}| zero’ will be translated into ‘make $x_{2r}$ zero’.

The rules just stated apply to lines that contain one, two, or three % signs in a row. Comments to \TeX can follow ‘%%%’. Five or more % signs should not be used.

Beside the normal input file, MFT also looks for a change file (e.g., ‘foo.ch’), which allows substitutions to be made in the translation. The change file follows the conventions of WEB, and it should be null if there are no changes. (Changes usually contain verbatim instructions to compensate for the fact that \TeX cannot format everything in an optimum way.)

There’s also a third input file (e.g., ‘plain.mft’), which is input before the other two. This file normally contains the ‘%%‘ formatting commands that are necessary to tune \TeX to a particular style of METAFONT code, so it is called the style file.

The output of MFT should be accompanied by the macros in a small package called mftmac.tex.

Caveat: This program is not as “bulletproof” as the other routines produced by Stanford’s \TeX project. It takes care of a great deal of tedious formatting, but it can produce strange output, because METAFONT is an extremely general language. Users should proofread their output carefully.

2* MFT uses a few features of the local Pascal compiler that may need to be changed in other installations:

1) Case statements have a default.

2) Input-output routines may need to be adapted for use with a particular character set and/or for printing messages on the user’s terminal.

These features are also present in the Pascal version of \TeX, where they are used in a similar (but more complex) way. System-dependent portions of MFT can be identified by looking at the entries for ‘system dependencies’ in the index below.

The “banner line” defined here should be changed whenever MFT is modified.

```
define my_name ≡ ‘mft’
define banner ≡ ‘This is MFT, Version 2.1’
```
3* The program begins with a fairly normal header, made up of pieces that will mostly be filled in later. The \texttt{MF} input comes from files \texttt{mf\_file}, \texttt{change\_file}, and \texttt{style\_file}; the \LaTeX\ output goes to file \texttt{tex\_file}.

If it is necessary to abort the job because of a fatal error, the program calls the \texttt{‘jump\_out’} procedure.

\begin{verbatim}
define class ≡ class_var
⟨Compiler directives 4⟩
program MFT (mf_file, change_file, style_file, tex_file);
  const ⟨Constants in the outer block 8⟩
  type ⟨Types in the outer block 12⟩
  var ⟨Globals in the outer block 9⟩
    ⟨Error handling procedures 29⟩
    ⟨Define parse_arguments 115⟩
  procedure initialize;
    var ⟨Local variables for initialization 14⟩
    begin kpse_set_program_name(argv[0], my_name); parse_arguments; (Set initial values 10); end;
\end{verbatim}

8* The following parameters are set big enough to handle the Computer Modern fonts, so they should be sufficient for most applications of MFT.

\begin{verbatim}
⟨Constants in the outer block 8⟩ ≡
  max_bytes = 60000;    { the number of bytes in tokens; must be less than 65536 }
  max_names = 6000;    { number of tokens }
  hash_size = 353;     { should be prime }
  buf_size = 3000;     { maximum length of input line }
  line_length = 79;    { lines of \LaTeX\ output have at most this many characters, should be less than 256 }
\end{verbatim}

This code is used in section 3*. 
The original Pascal compiler was designed in the late 60s, when six-bit character sets were common, so it did not make provision for lowercase letters. Nowadays, of course, we need to deal with both capital and small letters in a convenient way, especially in a program for font design; so the present specification of MFT has been written under the assumption that the Pascal compiler and run-time system permit the use of text files with more than 64 distinguishable characters. More precisely, we assume that the character set contains at least the letters and symbols associated with ASCII codes '40 through '176. If additional characters are present, MFT can be configured to work with them too.

Since we are dealing with more characters than were present in the first Pascal compilers, we have to decide what to call the associated data type. Some Pascals use the original name char for the characters in text files, even though there now are more than 64 such characters, while other Pascals consider char to be a 64-element subrange of a larger data type that has some other name.

In order to accommodate this difference, we shall use the name text_char to stand for the data type of the characters that are converted to and from ASCII code when they are input and output. We shall also assume that text_char consists of the elements chr(first_text_char) through chr(last_text_char), inclusive. The following definitions should be adjusted if necessary.

\begin{verbatim}
define text_char ≡ ASCII_code \{ the data type of characters in text files \}
define first_text_char = 0 \{ ordinal number of the smallest element of text_char \}
define last_text_char = 255 \{ ordinal number of the largest element of text_char \}
\end{verbatim}

The ASCII code is “standard” only to a certain extent, since many computer installations have found it advantageous to have ready access to more than 94 printing characters. If MFT is being used on a garden-variety Pascal for which only standard ASCII codes will appear in the input and output files, it doesn’t really matter what codes are specified in xchr[0 .. '37], but the safest policy is to blank everything out by using the code shown below.

However, other settings of xchr will make MFT more friendly on computers that have an extended character set, so that users can type things like ‘#’ instead of ‘<>’, and so that MFT can echo the page breaks found in its input. People with extended character sets can assign codes arbitrarily, giving an xchr equivalent to whatever characters the users of MFT are allowed to have in their input files. Appropriate changes to MFT’s char_class table should then be made. (Unlike \TeX, each installation of METAfont has a fixed assignment of category codes, called the char_class.) Such changes make portability of programs more difficult, so they should be introduced cautiously if at all.

\begin{verbatim}
for i ← 1 to '37 do xchr[i] ← chr(i);
for i ← '177 to '377 do xchr[i] ← chr(i);
\end{verbatim}
20* Terminal output is done by writing on file `term_out`, which is assumed to consist of characters of type `text_char`:

```plaintext
define term_out ≡ stdout
define print(#) ≡ write(term_out, #)  {‘print’ means write on the terminal}
define print_line(#) ≡ write_line(term_out, #)  {‘print’ and then start new line}
define new_line ≡ write_line(term_out)  {start new line on the terminal}
define print_nl(#) ≡ { print information starting on a new line}
begin new_line; print(#); end
```

21* Different systems have different ways of specifying that the output on a certain file will appear on the user’s terminal.

\[(\text{Set initial values 10} ) \oplus \equiv \{ \text{nothing need be done} \} \]

22* The `update_terminal` procedure is called when we want to make sure that everything we have output to the terminal so far has actually left the computer’s internal buffers and been sent.

```plaintext
define update_terminal ≡ fflush(term_out)  { empty the terminal output buffer }
```

24* The following code opens the input files.

```plaintext
procedure open_input;  { prepare to read inputs }
begin if metapost then mf_file ← kpse_open_file(cmdline(optind), kpse_mp_format)
else mf_file ← kpse_open_file(cmdline(optind), kpse-mf_format);
if change_name then
begin if metapost then change_file ← kpse_open_file(change_name, kpse_mp_format)
else change_file ← kpse_open_file(change_name, kpse-mf_format);
end;
styile_file ← kpse_open_file(style_name[0], kpse-mft_format); i_style_name ← 1;
end;
```

26* The following code opens `tex_file`. Since this file was listed in the program header, we assume that the Pascal runtime system has checked that a suitable external file name has been given.

\[(\text{Set initial values 10} ) \oplus \equiv \]

```plaintext
rewrite(tex_file, tex_name);
```
The `input Ln` procedure brings the next line of input from the specified file into the `buffer` array and returns the value `true`, unless the file has already been entirely read, in which case it returns `false`. The conventions of TeX are followed; i.e., ASCII code numbers representing the next line of the file are input into `buffer[0], buffer[1], ..., buffer[limit - 1]`; trailing blanks are ignored; and the global variable `limit` is set to the length of the line. The value of `limit` must be strictly less than `buf size`.

```
function input Ln(var f : text_file): boolean; { inputs a line or returns false }
  var final_limit: 0..buf_size; { limit without trailing blanks }
  begin limit ← 0; final_limit ← 0;
  if eof(f) then input Ln ← false
  else begin while ¬eoln(f) do
      begin buffer[limit] ← xord[getc(f)]; incr(limit);
      if buffer[limit - 1] ≠ "\n" then final_limit ← limit;
      if limit = buf_size then
        begin while ¬eoln(f) do vgetc(f);
        decr(limit); { keep buffer[buf_size] empty }
        if final_limit > limit then final_limit ← limit;
        print_nl("Input line too long"); loc ← 0; error;
      end;
    end;
    read_ln(f); limit ← final_limit; input Ln ← true;
  end;
end;
```
31* The \texttt{jump\_out} procedure cleans up, prints appropriate messages, and exits back to the operating system.

\begin{verbatim}
define fatal_error(#) ≡ begin new_line; print(#); error; mark_fatal; jump_out; end
\end{verbatim}

\begin{verbatim}
procedure jump_out;
  begin  { here files should be closed if the operating system requires it }
  ⟨Print the job history 113⟩;
  new_line;
  if (history ≠ spotless) ∧ (history ≠ harmless\_message) then uexit(1)
  else uexit(0);
  end;
\end{verbatim}
47* (Read from \textit{style\_file} and maybe turn off \textit{styling} 47*) ≡
begin incr(line);
if ∼\texttt{input\_ln(style\_file)} then
  begin if \texttt{i\_style\_name} \neq \texttt{n\_style\_name} then
    begin xfclose(\textit{style\_file}, \textit{style\_name}[\texttt{i\_style\_name} - 1]);
    \textit{style\_file} \leftarrow \texttt{kps\_open\_file(\textit{style\_name}[\texttt{i\_style\_name}], kps\_mft\_format)};
    \texttt{i\_style\_name} \leftarrow \texttt{i\_style\_name} + 1;
    end
  else begin styling \leftarrow \texttt{false};
    end;
  line \leftarrow 0;
  end;
end
This code is used in section 45.
§50  MFT changes for C and METAPOST  DATA STRUCTURES  409

63*  Initializing the primitive tokens.  Each token read by MFT is recognized as belonging to one of the following “types”:

- \texttt{define indentation} = 0  \{ internal code for space at beginning of a line \}
- \texttt{define end_of_line} = 1  \{ internal code for hypothetical token at end of a line \}
- \texttt{define end_of_file} = 2  \{ internal code for hypothetical token at end of the input \}
- \texttt{define verbatim} = 3  \{ internal code for the token ‘\%’ \}
- \texttt{define set_format} = 4  \{ internal code for the token ‘\%\%’ \}
- \texttt{define mft\_comment} = 5  \{ internal code for the token ‘\%\%\%’ \}
- \texttt{define min\_action\_type} = 6  \{ smallest code for tokens that produce “real” output \}
- \texttt{define numeric\_token} = 6  \{ internal code for tokens like ‘3.14159’ \}
- \texttt{define string\_token} = 7  \{ internal code for tokens like ‘\"pie\"’ \}
- \texttt{define min\_symbolic\_token} = 8  \{ smallest internal code for a symbolic token \}
- \texttt{define op} = 8  \{ internal code for tokens like ‘\sqrt’ \}
- \texttt{define command} = 9  \{ internal code for tokens like ‘addto’ \}
- \texttt{define endit} = 10  \{ internal code for tokens like ‘\fi’ \}
- \texttt{define binary} = 11  \{ internal code for tokens like ‘\and’ \}
- \texttt{define abinary} = 12  \{ internal code for tokens like ‘\+’ \}
- \texttt{define bbinary} = 13  \{ internal code for tokens like ‘\step’ \}
- \texttt{define ampersand} = 14  \{ internal code for the token ‘&’ \}
- \texttt{define python\_sub} = 15  \{ internal code for the token ‘++’ \}
- \texttt{define as\_is} = 16  \{ internal code for tokens like ‘[’ \}
- \texttt{define bold} = 17  \{ internal code for tokens like ‘\nullpen’ \}
- \texttt{define type\_name} = 18  \{ internal code for tokens like ‘numeric’ \}
- \texttt{define path\_join} = 19  \{ internal code for the token ‘..’ \}
- \texttt{define colon} = 20  \{ internal code for the token ‘:’ \}
- \texttt{define semicolon} = 21  \{ internal code for the token ‘;’ \}
- \texttt{define backslash} = 22  \{ internal code for the token ‘\’ \}
- \texttt{define double\_back} = 23  \{ internal code for the token ‘\\’ \}
- \texttt{define less\_or\_equal} = 24  \{ internal code for the token ‘\=<’ \}
- \texttt{define greater\_or\_equal} = 25  \{ internal code for the token ‘\>=’ \}
- \texttt{define not\_equal} = 26  \{ internal code for the token ‘\<\>’ \}
- \texttt{define sharp} = 27  \{ internal code for the token ‘\#’ \}
- \texttt{define comment} = 28  \{ internal code for the token ‘\%’ \}
- \texttt{define recomment} = 29  \{ internal code used to resume a comment after ‘!…!’ \}
- \texttt{define min\_suffix} = 30  \{ smallest code for symbolic tokens in suffixes \}
- \texttt{define internal} = 30  \{ internal code for tokens like ‘pausing’ \}
- \texttt{define input\_command} = 31  \{ internal code for tokens like ‘input’ \}
- \texttt{define btex\_code} = 32  \{ begin \TeX\ material (btex) \}
- \texttt{define verbatim\_code} = 33  \{ begin \TeX\ material (verbatimtext) \}
- \texttt{define etex\_marker} = 34  \{ end \TeX\ material (etex) \}
- \texttt{define special\_tag} = 35  \{ internal code for tags that take at most one subscript \}
- \texttt{define tag} = 36  \{ internal code for nonprimitive tokens \}

(\text{Assign the default value to ilk}[p] 63*) \equiv
ilk[p] \leftarrow tag

This code is used in section 62.
65* We begin with primitives common to METAfont and METAPOST.

The intended use of the macros above might not be immediately obvious, but the riddle is answered by the following:

\[ \langle \text{Store all the primitives } 65^* \rangle \equiv \]
\[
\begin{align*}
& \text{id}_\text{loc} \leftarrow 18; \\
& pr_2("."")("."")(\text{path}_\text{join}); \\

**Inputting the next token.** MFT’s lexical scanning routine is called \texttt{get.next}. This procedure inputs the next token of METAFONT input and puts its encoded meaning into two global variables, \texttt{cur.type} and \texttt{cur.tok}.

The \texttt{btex...etex} and \texttt{verbatimtex...etex} features need to be implemented at a low level in the scanning process. This is implemented by changing the behavior of the scanner via \texttt{scanner.status} global variable.

```
define normal = 0 { scanner.status at “quiet times” } define verbatimtext_flushing = 1 { scanner.status when moving verbatim \TeX{} material } define btex_flushing = 2 { scanner.status when moving \TeX{} code }
```

(Globals in the outer block 9) +/-

\texttt{cur.type}: eight_bits; \{ type of token just scanned \}

\texttt{cur.tok}: integer; \{ hash table or buffer location \}

\texttt{prev.type}: eight_bits; \{ previous value of \texttt{cur.type} \}

\texttt{prev.tok}: integer; \{ previous value of \texttt{cur.tok} \}

\texttt{scanner.status}: normal .. btex_flushing; \{ are we scanning at high speed? \}

---

**If changes are made to accommodate non-ASCII character sets, they should be essentially the same in MFT as in METAFONT.** However, MFT has an additional class number, the \texttt{end.line.class}, which is used only for the special character \texttt{carriage_return} that is placed at the end of the input buffer.

```
define carriage_return = ‘15 \{ special code placed in buffer[limit] \}
```

(\texttt{Set initial values 10}) +/-

```
for i ← "0" to "9" do char_class[i] ← digit_class;
char_class["-"], char_class["+"], char_class["\*"], char_class["\%"], char_class["\^"], char_class["\_"], char_class["<"], char_class[">"], char_class[":"], char_class["\;"], char_class["\:"], char_class["\?"], char_class["\?"], char_class["\?"], char_class["\?"], char_class["\?"], char_class["\?"], char_class["\?"], char_class["\?"], char_class["\?"], char_class[""]]
```

---

Inputting the next token.

&\text{done: emit(\text{numeric\_token})} \\
\end{align*}

This code is used in section 80.
MFT calls `flush_buffer(out_ptr, false)` before it has input anything. We initialize the output variables so that the first line of the output file will be `\input mftmac` or `\input mptmac` if a METAPOST file is converted.

\begin{verbatim}
\verb+(Set initial values 10)+
\begin{verbatim}
ext_ptr ← 1; out_buf[1] ← " \n"; out_line ← 1;
if metapost then
\verb+begin write(tex_file, \"\input mptmac\");+
\verb+end+
else write(tex_file, \"\input mftmac\");
\end{verbatim}
\end{verbatim}
97* Translation. The main work of MFT is accomplished by a routine that translates the tokens, one by one, with a limited amount of lookahead/lookbehind. Automata theorists might loosely call this a “finite state transducer,” because the flow of control is comparatively simple.

procedure do_the_translation;
  label restart, reswitch, done, exit;
  var k: 0 .. buf_size; { looks ahead in the buffer }
    t: integer; { type that spreads to new tokens }
  begin restart: if out_ptr > 0 then flush_buffer(out_ptr, false);
    empty_buffer ← true;
  loop begin get_next;
    if start_of_line then ⟨ Do special actions at the start of a line 98 ⟩;
    reswitch: case cur_type of
      numeric_token: ⟨ Translate a numeric token or a fraction 105 ⟩;
      string_token: ⟨ Translate a string token 99 ⟩;
      verbatim_code, btex_code: ⟨ Copy TeX material 125* ⟩;
      indentation: out_str(tr_quad);
      end_of_line, mft_comment: ⟨ Wind up a line of translation and goto restart, or finish a |...| segment and goto reswitch 110 ⟩;
      end_of_file: return;
    ⟨ Cases that translate primitive tokens 100 ⟩
    comment, recomment: ⟨ Translate a comment and goto restart, unless there’s a |...| segment 108 ⟩;
    verbatim: ⟨ Copy the rest of the current input line to the output, then goto restart 109 ⟩;
    set_format: ⟨ Change the translation format of tokens, and goto restart or reswitch 111 ⟩;
    internal, special_tag, tag: ⟨ Translate a tag and possible subscript 106 ⟩;
  end; { all cases have been listed }
  end;
  exit: end;
112* The main program. Let’s put it all together now: MFT starts and ends here.

```plaintext
begin initialize;  { beginning of the main program }
print(banner);   { print a “banner line” }
println(version_string);  { Store all the primitives 65*);
⟨ Store all the translations 73⟩;
⟨ Initialize the input system 44⟩;
do_the_translation;  { Check that all changes have been read 49};
⟨ Print the job history 113⟩;
newline;
if (history ≠ spotless) ∧ (history ≠ harmless_message) then uexit(1)
else uexit(0);
end.
```
114* System-dependent changes. The user calls MFT with arguments on the command line. These are either filenames or flags (beginning with ‘-‘). The following globals are for communicating the user’s desires to the rest of the program. The various name variables contain strings with the full names of those files, as UNIX knows them.

```plaintext
define max_style_name = 32
⟨ Globals in the outer block 9 ⟩ +≡
  change_name, tex_name: const c_string;
  style_name: array [0..max_style_name - 1] of const c_string;
  n_style_name: c_int_type;  { Number of values in style_name array. }
  i_style_name: c_int_type;  { The next style_name. }
  metapost: c_int_type;  { true for METAPOST, false for METAFONT }
```
Look at the command line arguments and set the `name` variables accordingly.

At least one file name must be present as the first argument: the `mf` file. It may have an extension, or it may omit it to get `.mf` added. If there is only one file name, the output file name is formed by replacing the `mf` file name extension by `.tex`. Thus, the command line `mf foo` implies the use of the `METAPOST` input file `foo.mf` and the output file `foo.tex`. If this style of command line, with only one argument, is used, the default style file, `plain.mft`, will be used to provide basic formatting.

```plaintext
define argument_is(#) ≡ (strcmp(long_options[option_index].name., #) = 0)
(Define `parse_arguments` 115*)

procedure parse_arguments;
const n_options = 5; { Pascal won’t count array lengths for us. }
var long_options: array [0..n_options] of getopt_struct;
getopt_return_val: integer; option_index: c_int_type; current_option: 0..n_options;
suffix: const c_string;

begin {Initialize the option variables 121*};
(Define the option table 116*);
n_style_name ← 0;
repeat getopt_return_val ← getopt_long_only(argc, argv, ´*, long_options, address_of(option_index));
if getopt_return_val = -1 then
begin do_nothing; { End of arguments; we exit the loop below. }
end
else if getopt_return_val = "?" then
begin usage(my_name);
end
else if argument_is(´help´) then
begin usage_help(MFT_HELP, nil);
end

Assign the default value to \textit{ilk}[p] 63* Used in section 62.
(Branch on the \textit{class}, scan the token; \textbf{return} directly if the token is special, or \textbf{goto} found if it needs to be looked up 81*) Used in section 80.
(Bring in a new line of input; \textbf{return} if the file has ended 85) Used in section 80.
(Cases that translate primitive tokens 100, 101, 102, 103) Used in section 97*.
(Change the translation format of tokens, and \textbf{goto} restart or \textit{reswitch} 111} Used in section 97*.
(Change name \textit{p} with current token, \textbf{goto} found if equal 61} Used in section 60.
(Compiler directives 4} Used in section 3*.
(Compute the hash code \textit{h} 59) Used in section 58.
(Compute the name location \textit{p} 60} Used in section 58.
(Compute the name location \textit{p} 60} Used in section 58.
(Decry the invalid character and \textbf{goto} switch 84} Used in section 81*.
(Decry the missing string delimiter and \textbf{goto} switch 83} Used in section 82.
(Define the option table 116*, 117*, 118*, 119*, 120*, 122*) Used in section 115*.
(Define \textit{parse_arguments} 115*) Used in section 3*.
(Do special actions at the start of a line 98} Used in section 97*.
(Enter a new name into the table at position \textit{p} 62} Used in section 58.
(Error handling procedures 29, 31*) Used in section 3*.
(Get a string token and \textbf{return} 82} Used in section 81*.
(Globals in the outer block 9, 15, 23, 25, 27, 34, 36, 51, 53, 55, 72, 74, 75*, 77, 78, 86, 114*) Used in section 3*.
(If the current line starts with $@y$, report any discrepancies and \textbf{return} 43} Used in section 42.
(Initialize the input system 44} Used in section 112*.
(Initialize the option variables 121*) Used in section 115*.
(Local variables for initialization 14, 56) Used in section 3*.
(Move buffer and \textit{limit} to \textit{change_buffer} and \textit{change_limit} 41} Used in sections 38 and 42.
(Print error location based on input buffer 30) Used in section 29.
(Read from \textit{change_file} and maybe turn off changing 48} Used in section 45.
(Read from \textit{mf_file} and maybe turn on changing 46) Used in section 45.
(Read from \textit{style_file} and maybe turn off styling 47*) Used in section 45.
(Scan the file name and output it in \texttt{typewriter type} 104} Used in section 103.
(Set initial values 10, 16, 17*, 18, 21*, 26*, 54, 57, 76, 79*, 88*, 90} Used in section 3*.
(Skip over comment lines in the change file; \textbf{return} if end of file 39} Used in section 38.
(Skip to the next nonblank line; \textbf{return} if end of file 40) Used in section 38.
(Store all the primitives 65*, 66*, 67*, 68*, 69*, 70*, 71*, 123*, 124*) Used in section 112*.
(Store all the translations 73} Used in section 112*.
(Translate a comment and \textbf{goto} restart, unless there’s a \ldots \textit{segment} 108} Used in section 97*.
(Translate a numeric token or a fraction 105} Used in section 97*.
(Translate a string token 99} Used in section 97*.
(Translate a subscript 107} Used in section 106.
(Translate a tag and possible subscript 106} Used in section 97*.
(Types in the outer block 12, 13*, 50, 52)} Used in section 3*.
(Wind up a line of translation and \textbf{goto} restart, or finish a \ldots \textit{segment} and \textbf{goto} \textit{reswitch} 110} Used in section 97*.
