Luawidow-control is a Plain TEX/LaTEX/ConTEXt/OpTEX package that removes widows and orphans without any user intervention. Using the power of LuaTeX, it does so without stretching any glue or shortening any pages or columns. Instead, luawidow-control automatically lengthens a paragraph on a page or column where a widow or orphan would otherwise occur.

Quick Start

Ensure that your TEX Live/MikTeX distribution is up-to-date. Then, LaTeX users just need to place \usepackage{lua-widow-control} in the preamble of your document. For more details, see the Usage sections.

**MOTIVATION**

\( \text{T}_{\text{E}}\text{X} \) provides top-notch typesetting: even 40 years after its first release, no other program produces higher quality mathematical typesetting, and its paragraph-breaking algorithm is still state-of-the-art. However, its page breaking is not quite as sophisticated as its paragraph breaking and thus suffers from some minor issues.

Unmodified \( \text{T}_{\text{E}}\text{X} \) typically has only 2 ways of dealing with widows and orphans: it can either shorten a page by 1 line, or it can stretch out some vertical whitespace. \( \text{T}_{\text{E}}\text{X} \) was designed for mathematical and scientific typesetting, where a typical page has multiple section headings, tables, figures, and equations. For this style of document, \( \text{T}_{\text{E}}\text{X} \)'s default behavior works quite well; however, for prose or
any other document composed almost entirely of text, there is no vertical whitespace to stretch.

Since there were no ready-made and fully-automated solutions to remove widows and orphans from all types of documents, I decided to create lua-widow-control.

**W I D O W S A N D O R P H A N S**

**Widows**

Widows occur when when the majority of a paragraph is on one page or column, but the last line is on the following page or column. Widows are undesirable for both aesthetics and readability. Aesthetically, it looks quite odd for a lone line to be at the start of the page. Functionally, the separation of a paragraph and its last line disconnects the two, causing the reader to lose context for the widowed line.

**Orphans**

Orphans are when the first line of a paragraph occurs on the page or column before the remainder of they paragraph. They are not nearly as distracting for the reader, but they are still not ideal. Visually, widows and orphans are about equally disruptive; however, orphans tend not to decrease the legibility of a text as much as widows do, so they tend to be ignored more often.

**Broken Hyphens**

“Broken” hyphens occur whenever a page break occurs part way through a hyphenated word. These really have nothing to do with widows and orphans; however, TeX treats broken hyphens exactly the same as it does widows and orphans. In addition, breaking a word across two pages is at almost as bad for the reader as widows and orphans; therefore, lua-widow-control treats broken hyphens exactly the same way as it treats widows and orphans.

![Figure 1](image-url)

**Figure 1** A visual comparison of widows and orphans.
**tex's pagination**

**Algorithm**

It is tricky to understand how lua-widow-control works if you aren’t familiar with how \TeX\ breaks pages and columns. Chapter 15 of *The \TeX\ Book*\(^1\) (“How \TeX\ Makes Lines into Pages”) is the best reference for this; however, it goes into much more detail than most users require. As a supplemental resource, I can also recommend Section 27 of *\TeX\ by Topic*\(^2\), available online for free. Below follows a very simplified (and likely error-ridden) summary of \TeX’s page breaking algorithm:

\TeX\ fills the page with lines and other objects until the next object will no longer fit. Once no more objects will fit, \TeX, will align the bottom of the last line with the bottom of the page by stretching any vertical spaces.

However, some objects have penalties attached. These penalties make \TeX\ treat the object as if it is longer or shorter for the sake of page breaking. By default, \TeX\ assigns a penalties to the first and last lines of a paragraph (widows and orphans). This makes \TeX\ treat them as if they are larger or smaller than their actual size such that \TeX\ tends not to break them up.

One important note: once \TeX\ begins breaking a page, it never goes back and modifies any content on the page. Page breaking is a localized algorithm, without any backtracking.

**Behavior**

Of course, this algorithm doesn’t allow us to intuitively understand how \TeX\ deals with widows and orphans.

Due to the penalties attached to widows and orphans, \TeX\ treats them as if they are longer than they actually are. Widows and orphans with small penalties attached—like \LaTeX\’s default values of 150—are only treated as slightly taller than 1 line, while widows and orphans with large penalties—values near 10 000—are treated as if they are 2 lines tall. Because potential widow and orphan lines are broken as if they are taller than they actually are, \TeX\ will tend to group them together on the same pages.

However, when these lines are moved as a group, \TeX\ will have to make a page or column with less lines. “**Demonstration**” goes into further detail about how \TeX\ deals with these too-short pages or columns. The main takeaway is that for a page exclusively filled with text, all of \TeX\’s builtin solutions come with compromises.
OTHER SOLUTIONS

There have been a few previous attempts to improve upon \TeX’s previously-discussed widow and orphan-handling abilities; however, none of these have been able to automatically remove widows and orphans without stretching any glue or shortening any pages.

Strategies against widows\textsuperscript{3} and Managing forlorn paragraph lines in \LaTeX\textsuperscript{4} both begin with comprehensive discussions of the methods of preventing widows and orphans. They both agree that widows and orphans are bad and ought to be avoided; however, they each differ in solutions. Strategies\textsuperscript{3} proposes an output routine that reduces the length of facing pages by 1 line when necessary to remove widows and orphans while Managing\textsuperscript{4} proposes that the author manually rewrites or adjusts the \verb|\looseness| when needed.

Paragraph callback to help with widows/orphans hand tuning\textsuperscript{5} contains a file \verb|widow-assist.lua| that automatically detects which paragraphs can be safely shortened or lengthened by 1 line. The widows-and-orphans package\textsuperscript{6} alerts the author to the pages that contain widows or orphans. Combined, these packages make it very simple for the author to quickly remove widows and orphans by adjusting the \verb|\looseness| values; however, it still requires the author to make manual source changes after each revision.

Lua-widow-control is essentially just a combination of \verb|widow-assist.lua|\textsuperscript{5} and widows-and-orphans:\textsuperscript{6} when the \verb|\outputpenalty| shows that a widow or orphan occurred, Lua is used to find a stretchable paragraph. What lua-widow-control adds on top of these packages is automation: lua-widow-control eliminates the requirement for any manual adjustments.

DEMONSTRATION

Although \TeX’s page breaking algorithm is quite simple, it can lead to some fairly complex behaviors when widows and orphans are involved. The usual choices are to either ignore them, stretch some glue, or shorten the page. Table 1 has a visual demonstration of some of these behaviors and how lua-widow-control differs from the defaults.

Ignore

As you can see, the last line of the page is on a separate page from the rest of its paragraph, creating a widow. This is usually pretty distracting for the reader, so it is best avoided wherever possible.
Lua-widow-control can remove most widows and orphans from a document, *without* stretching any glue or shortening any pages.

It does so by automatically lengthening a paragraph on a page where a widow or orphan would otherwise occur. While TeX breaks paragraphs into their natural length, lua-widow-control is breaking the paragraph 1 line longer than its natural length. TeX's paragraph is output to the page, but lua-widow-control's paragraph is just stored for later. When a widow or orphan occurs, lua-widow-control can take over. It selects the previously-saved paragraph with the least badness; then, it replaces TeX's paragraph with its saved paragraph. This increases the text block height of the page by 1 line.

Now, the last line of the current page can be pushed to the top of the next page. This removes the widow or the orphan without creating any additional work.

\parskip=0pt
\clubpenalty=0
\widowpenalty=0

Lua-widow-control can remove most widows and orphans from a document, *without* stretching any glue or shortening any pages.

\usepackage{lua-widow-control}
\parskip=0pt
\clubpenalty=10000
\widowpenalty=10000

Table 1  A visual comparison of various automated widow handling techniques.
Shorten
This page did not leave any widows, but it did shorten the previous page by 1 line. Sometimes this is acceptable, but usually it looks bad because each page will have different text-block heights. This can make the pages look quite uneven, especially when typesetting with columns or in a book with facing pages.

Stretch
This page also has no widows and it has a flushed bottom margin. However, the space between each paragraph had to be stretched.

If this page had many equations, headings, and other elements with natural space between them, the stretched out space would be much less noticeable. \TeX was designed for mathematical typesetting, so it makes sense that this is its default behavior. However, in a page with mostly text, these paragraph gaps can look unsightly.

In addition, this method is incompatible with typesetting on a grid since all glue stretch must be quantized to the height of a line.

lua-widow-control
Lua-widow-control has none of these issues: it eliminates the widows in a document while keeping a flushed bottom margin and constant paragraph spacing.

To do so, lua-widow-control lengthened the second paragraph by one line. If you look closely, you can see that this stretched the interword spaces. This stretching is noticeable when typesetting in a narrow text block, but it becomes nearly imperceptible with larger widths.

Lua-widow-control automatically finds the “best” paragraph to stretch, so the increase in interword spaces should almost always be minimal.

INSTALATION
Most up-to-date \TeX Live and MiKTeX systems should already have lua-widow-control installed. However, a manual installation may occasionally be required.

\TeX Live
Run `tlmgr install lua-widow-control` in a terminal, or install using the “\TeX Live Manager” GUI.

MiKTeX
Run `mpm --install=lua-widow-control` in a terminal, or install using the “MiKTeX Maintenance” GUI.

ConTeXt MKIV Standalone
Run `first-setup.sh --modules="lua-widow-control"` in a terminal or install manually.
Currently, ConTeXt mkxl (luametaTeX) users must manually install the package. Most other users will be better served by using the lua-widow-control supplied by TeX Live and MikTeX; however, all users may manually install the package if desired. The procedure should be fairly similar regardless of your os, TeX distribution, or format.

**Steps**

1. Download lua-widow-control.tds.zip from CTAN or GitHub.
2. Unzip the release into your TEXMFLOCAL/ directory. (You can find its location by running kpsewhich --var-value TEXMFHOME in a terminal)
3. Refresh the filename database:
   - ConTeXt: mtxrun --generate
   - TeX Live: mktexlsr
   - MikTeX: initexmf --update-fndb

**Dependencies**

Lua-widow-control does have a few dependencies; however, these will almost certainly be met by all but the most minimal of TeX installations.

**Plain TeX**

Lua-widow-control requires LuaTeX (≥ 0.85) and the most recent version of lua-texbase (2015/10/04). Any version of TeX Live ≥ 2016 will meet these requirements.

**LaTeX**

Lua-widow-control requires LuaTeX (≥ 0.85), LaTeX (≥ 2020/10/01), and microtype (any version). Any version of TeX Live ≥ 2021 will meet these requirements.

Lua-widow-control also supports a “legacy” mode for older LaTeX kernels. This uses an older version of the LaTeX code while still using the most recent Lua code. This mode requires LuaTeX (≥ 0.85), LaTeX (≥ 2015/01/01), microtype (any version), and etoolbox (any version). Any version of TeX Live ≥ 2016 will meet these requirements.

Please note that when running in legacy mode, you cannot use the key–value interface. Instead, you should follow the "Plain TeX" interface.

**ConTeXt**

Lua-widow-control supports both ConTeXt mkxl (luametaTeX) and ConTeXt mkiv (LuaTeX).

**OpTeX**

Lua-widow-control works with any version of OpTeX and has no dependencies.
LOADING THE PACKAGE

Plain TeX \input lua-widow-control
\LaTeX \usepackage{lua-widow-control}
\ConTeXt \usemodule{lua-widow-control}
\OpTeX \loadlua{lua-widow-control}

OPTIONS

Lua-widow-control is automatically enabled with the default settings as soon as you load it. Most users should not need to configure lua-widow-control; however, the packages provides a few commands.

Overview \LaTeX users can set the options either when loading the package (\usepackage{⟨options⟩}{lua-widow-control}) or at any point using \lwcsetup{⟨options⟩}.
\ConTeXt users should always use the \setuplwc{⟨options⟩} command.
Plain TeX and OpTeX are a little different. Some options have commands provided (i.e., \lwcemergencystretch = ⟨dimension⟩), while others must be set manually (i.e., \directlua{lwc.debug = true}).
Also, please note that not all commands are provided for all formats.

Enabling Lua-widow-control is enabled by default as soon as you load it. Nevertheless, you may need to explicitly reenable it if you have previously disabled it.
Plain TeX/OpTeX \lwcenable
\LaTeX \lwcsetup{enable}
\ConTeXt \setuplwc[state = start]

Disabling Plain TeX/OpTeX \lwcdisable
\LaTeX \lwcsetup{disable}
\ConTeXt \setuplwc[state = stop]
**Strict Mode**

By default, lua-widow-control takes all possible measures to remove widows and orphans. This normally works out pretty well; however, sometimes these measures may be a little more aggressive than certain users want.

Lua-widow-control offers a “strict” mode that will only make modification to the page that are near-imperceptible to remove widows and orphans.

\LATEX\>`\lwcsetup{strict}`

Internally, this sets `emergencystretch = 0pt, max-cost = 5000`, and `no-break = warn`.

\emergency\stretch

You can configure the `\emergencystretch` used when stretching a paragraph. The default value is 3 em.

Lua-widow-control will only use the `\emergencystretch` when it cannot lengthen a paragraph in any other way, so it is fairly safe to set this to a large value. \TeX still accumulates badness when `\emergencystretch` is used, so it’s pretty rare that a paragraph that requires any `\emergencystretch` will actually be used on the page.

Plain \TeX/Op\TeX\>`\lwcemergencystretch = \langle dimension \rangle`

\LATEX\>`\lwcsetup{emergencystretch = \langle dimension \rangle}`

Con\TeXt\>`\setup\lwc[emergencystretch = \langle dimension \rangle]`

**Selectively Disabling**

Sometimes, you may want to disable lua-widow-control for certain commands where stretching is undesirable. For example, you typically wouldn’t want section headings to be stretched.

You could just disable then reenable lua-widow-control every time that you use the command; however, lua-widow-control provides a convenience macro that will do this automatically for you.

Lua-widow-control automatically patches the default \LATEX, Con\TeXt, and Plain \TeX section commands, so you shouldn’t need to patch these yourself; however, lua-widow-control does not patch the non-standard section commands provided by memoir, KOMA-script, titlesec, Op\TeX, and others. You’ll need to add these yourself.

Plain \TeX\>`\lwcdisablecmd{{\langle macro \rangle}}`

\LATEX\>`\lwcsetup{disablecmds = {{\langle macroone \rangle}, {\langle macrotwo \rangle}}}`

Con\TeXt\>`\prependtoks\lwc@patch@pre\to\everybefore{\langle hook \rangle}`
>`\prependtoks\lwc@patch@pre\to\everyafter{\langle hook \rangle}`
Widow and Orphan Penalties

You can also manually adjust the penalties that \TeX assigns to widows, orphans, and broken hyphens. Usually, the defaults are fine, but advanced users may want to change them.

Plain \TeX/Op\TeX

\widowpenalty = ⟨integer⟩
\clubpenalty = ⟨integer⟩
\brokenpenalty = ⟨integer⟩

\LaTeX

\lwcsetup\{\widowpenalty = \langle\text{integer}\rangle\}
\lwcsetup\{\orphanpenalty = \langle\text{integer}\rangle\}
\lwcsetup\{\brokenpenalty = \langle\text{integer}\rangle\}

\Context

\setuplwc\[\widowpenalty = \langle\text{integer}\rangle\]
\setuplwc\[\orphanpenalty = \langle\text{integer}\rangle\]
\setuplwc\[\brokenpenalty = \langle\text{integer}\rangle\]

Some suitable integers:

| Ignore widows/orphans | 0 |
| Default               | 1 |
| Disable lua-widow-control | 10000 |

\nobreak Behaviour

When lua-widow-control encounters an orphan, it removes it by removing the orphaned line to the next page. However, sometimes, an orphan is immediately preceded by a section heading or a \nobreak command. By moving the orphan to the next page, you would naïvely separate a section (or other such material) from the line that follows. This really ought to be avoided, so lua-widow-control provides some options to avoid this.

Plain \TeX/Op\TeX

\directlua\{lwc.nobreak Behaviour = "⟨value⟩"\}

\LaTeX

\lwcsetup\{nobreak = ⟨value⟩\}
\lwcsetup\{orphanpenalty = ⟨integer⟩\}
\lwcsetup\{brokenpenalty = ⟨integer⟩\}

\Context

\setuplwc\[nobreak = ⟨value⟩\]
\setuplwc\[orphanpenalty = ⟨integer⟩\]
\setuplwc\[brokenpenalty = ⟨integer⟩\]

The default value, keep, keeps the section heading with the orphan by moving both to the next page.

The value split splits up the section heading and the orphan by moving the orphan to the next page while leaving the heading behind. This is usually a bad idea.
The value warn causes lua-widow-control to give up on the page and do nothing, leaving an orphaned line. Lua-widow-control warns the user so that they can manually remove the orphan.

**Maximum Cost**

When \TeX breaks a paragraph, it scores it by the number of “demerits”. The demerits for a paragraph is the sum of the squared badnesses for each line, plus any “additional demerits” added for any other reason. The badness for a line is proportional the cube of the glue stretch ratio, so demerits grow with the sixth power of glue stretch.

To choose the “best” paragraph on the page, lua-widow-control uses a “cost function” $C$ that is initially defined as

$$C = \frac{d}{\sqrt{l}}$$

where $d$ is the total demerits of the paragraph, and $l$ is the number of lines in the paragraph.

By default, lua-widow-control just selects the paragraph on the page with the lowest cost; however, you can configure it to only select paragraphs below a selected cost. If there aren’t any paragraphs below the set threshold, then lua-widow-control won’t remove the widow or orphan and will instead issue a warning.

Plain \TeX/Op\TeX

\begin{verbatim}
\lwcmaxcost = ⟨integer⟩
\end{verbatim}

\LaTeX

\begin{verbatim}
\lwcsetup{max-cost = ⟨integer⟩}
\end{verbatim}

Con\TeXt

\begin{verbatim}
\setuplwc[maxcost = ⟨integer⟩]
\end{verbatim}

Very advanced users may also set a custom cost function by redefining the \texttt{lwc.paragraph\_cost}(demerits, lines) function.

**Debug Mode**

Lua-widow-control offers a “debug” mode that prints extra information in the log files. This may be helpful to understand how lua-widow-control is processing paragraphs and pages.
Plain \TeX/\OpTeX\n\directlua{lwc.debug = true}
\directlua{lwc.debug = false}

\LaTeX\n\lwcsetup{debug = true}
\lwcsetup{debug = false}

\Con\TeXt\n\setuplwc[state = start]
\setuplwc[state = stop]

\textbf{Columns}

Since \TeX implements column breaking and page breaking through the same internal mechanisms, lua-widow-control should remove widows and orphans between columns just as well as it does with widows and orphans between pages. This has been tested with the standard \LaTeX\ class option \texttt{twocolumn} and the two-column output routine from Chapter 23 of The \TeX\book.\footnote{1} Lua-widow-control should presumably work with any other multi-column implementation; however, due to the diversity and complexity of output routines, this cannot be guaranteed.

\textbf{Known Issues}

- Lua-widow-control will rarely fail to correctly move the last line on an expanded page to the next page in documents with very small paper sizes. (Issue #19)

- When a 3-line paragraph is at the end of a page forming a widow, lua-widow-control will remove the widow; however, it will leave an orphan. This issue is inherent to any process that removes widows through paragraph expansion and is thus unavoidable. Orphans are better than widows, so this is still an improvement.

- Sometimes a widow or orphan cannot be eliminated because no paragraph has enough “stretch”. This can sometimes be remediated by increasing lua-widow-control’s \texttt{\emergencystretch}; however, some pages just don’t have enough “stretchy” paragraphs. Long paragraphs with short words tend to be “stretchier” than short paragraphs with long words since these long paragraphs will have more interword glue. Narrow columns also stretch easier than wide columns since you need to expand a paragraph by less to make a new line.

- When running under luameta\TeX, the log may be filled with lines like “\luatex
warning > tex: left parfill skip is gone”. This is harmless and can be ignored. (Issue #7)

- Lua-widow-control will rarely raise a “Circular node list detected!” warning. This occurs when the replacement paragraph node list loops back on itself. This is usually harmless, but can rarely cause the entire compile to completely fail. (Issue #9)

- \TeX{} may warn you about over or underfull vboxes on pages where lua-widow-control removed a widow or orphan. This is a false alarm and can be ignored. (Issue #8)

- If there is a footnote on the last line of the page with a widow or orphan, lua-widow-control will sometimes move the “footnote mark” but not the “footnote text”, thus breaking up a footnote. (Issue #26)

**The Algorithm**

Lua-widow-control uses a fairly simple algorithm to eliminate widows and orphans. It is pretty basic, but there are a few subtleties. Please see *Implementation* for a full listing of the source code.

**Paragraph Breaking**

First, lua-widow-control hooks into the paragraph breaking process. Before a paragraph is broken by \TeX{}, lua-widow-control grabs the unbroken paragraph. Lua-widow-control then breaks the paragraph 1 line longer than its natural length and stores it for later, \textit{without} interfering with how \TeX{} breaks paragraphs into their natural length.

After \TeX{} has broken its paragraph into its natural length, lua-widow-control appears once again. Before the broken paragraph is added to the main vertical list, lua-widow-control tags the first and last nodes of the paragraph. These tags create a relationship between the previously-saved lengthened paragraph and the start/end of the naturally-typeset paragraph on the page.

**Page Breaking**

lua-widow-control intercepts \texttt{\box255} immediately before the output routine.

First, lua-widow-control analyzes the \texttt{\outputpenalty} of the page or column. If the page was broken at a widow or orphan, the \texttt{\outputpenalty} will equal either \texttt{\widowpenalty} or \texttt{\orphanpenalty}. If the \texttt{\outputpenalty} is not indicative of a widow or orphan, lua-widow-control will stop and return \texttt{\box255} unmodified.

At this point, we know that we have a widow or orphan on the page, so we must lengthen the page by 1 line. We iterate through the list of saved paragraphs to
find the lengthened paragraph with the least cost. Once we’ve selected a paragraph to replace, we can now traverse through the page to find the original version of this paragraph that \TeX{} originally typeset. Once we find the original paragraph, we “splice” the lengthened paragraph in the place of the original.

Since the page is now 1 line longer than it was before, we pull the last line off of the page to bring it back to its original length. We place the line onto the top of the recent contributions list so that it is added to the start of the next page. Now, we can return the new, widow-free page to the output routine.

**Contributions**

If you have any issues with lua-widow-control, please create an issue at the project’s GitHub page. Or, if you think that you can solve any of the “Known Issues” or add any new features, submit a PR. Thanks!

**License**

Lua-widow-control is licensed under the Mozilla Public License, version 2.0 or greater. The documentation is licensed under cc-by-sa, version 4.0 or greater as well as the mpl.

Please note that a compiled document is not considered to be an “Executable Form” as defined by the mpl. The mpl and cc-by-sa licenses only apply to you if you distribute the lua-widow-control source code or documentation.

--- Silence the luatexbase "Enabling/Removing <callback>" info messages
---
--- Every time that a paragraph is typeset, \lwc/ hooks in
--- and typesets the paragraph 1 line longer. Some of these longer paragraphs
--- will have pretty bad badness values, so TeX will issue an over/underfull
--- hbox warning. To block these warnings, we hook into the `hpack_quality`
--- callback and disable it so that no warning is generated.
---
--- However, each time that we enable/disable the null `hpack_quality` callback,
--- luatexbase puts an info message in the log. This completely fills the log file
--- with useless error messages, so we disable it here.
---
--- This uses the Lua `debug` library to internally modify the log upvalue in the
--- `add_to_callback` function. This is almost certainly a terrible idea, but I don't
--- know of a better way.

\starttext
  \Lwc/ can remove most widows and orphans from a document. \textit{\emph{without}} stretching any glue or shortening any pages.

  It does so by automatically lengthening a paragraph on a page where a widow or orphan would otherwise occur. While $\LaTeX$ breaks paragraphs into their natural length, $\lwc/\$ is breaking the paragraph 1-line longer than its natural length. $\LaTeX$'s paragraph is output to the page, but $\lwc/\$'s paragraph is just stored for later. When a widow or orphan occurs, $\lwc/\$ can take over. It selects the previously-saved paragraph with the least badness; then, it replaces $\LaTeX$'s paragraph with its saved paragraph. This increases the text block height of the page by 1-line.
Now, the last line of the current page can be pushed to the top of the next page. This removes the widow or the orphan without creating any additional work.
